Abstract

Four species of Horismenus (Hymenoptera: Eulophidae) associated with Acanthoscelides spp. (Coleoptera: Bruchidae), three of which are also associated with Phaseolus spp., are treated. One of the species, H. butcheri, is described as new and the remaining three species are redescribed. All four species are diagnosed in a key. A lectotype is designated for Holocelte productus Ashmead.

Key words: Horismenus, Eulophidae, Acanthoscelides, Bruchidae, species description, revision, Phaseolus

Introduction

This taxonomic work was triggered by an ongoing project studying the effects of plant variability on host-parasitoid interactions and consequences for the genetic population structure of these organisms. Female parasitoids are known to rely on volatile chemical cues emanating from the plant on which their host feeds to localise their hosts (Turlings & Wäckers 2004). While the parasitoid’s host-location behaviour and performance can clearly be enhanced by the use of these chemical cues, the impact of plant features such as allelochemistry, nutritional quality or morphology can also alter the parasitoid reproductive success (Barbosa and Benrey 1998; Turlings and Benrey 1998; Karban and Hue 1999). The potential impact of plants on the parasitoids reproductive success raises the question whether plant quality could influence the genetic population structure of the parasitoid populations. A previous study has shown that the performance (parasitism rate, development time and sex ratio) and host-location behaviour of a parasitoid attacking bruchid beetles that feed on the seeds of the genus Phaseolus are greatly affected by the plant species and variety on which the bruchid host feeds (Benrey et al. 1998).
For this study, wild bean samples (*Phaseolus vulgaris*, *P. lunatus* and *P. coccineus*) were collected during three consecutive years (2001-2003, between December and April) in Mexico. The samples (from a total of 49 populations) were found to be infested with bruchid beetles of two genera: *Acanthoscelides* (99.7%) and *Zabrotes* (0.3%) (Coleoptera: Bruchidae). Members of a parasitoid guild comprising the following families were reared from this material: Eulophidae (*Horismenus* spp., 59.1%), Eupelmidae (*Eupelmus* sp., 16.8%), Eurytomidae (*Chryseida* sp. 13.4%), Braconidae (*Stenocorse bruchivora*, 7.7%), Torymidae (*Microdontomerus* sp., 2.9%) and Pteromalidae (*Dinarmus* sp., 0.1%). The genus *Horismenus* was the most abundant parasitoid group and was selected for the second author’s population genetic project.

Parasitoids often display plant specificity (Godfray 1994). As preliminary genetic data on a pool of undetermined *Horismenus* individuals showed that specimens originating from different *Phaseolus* species were highly genetically differentiated, we suspected that our initial sample contained several species. In order to avoid misinterpretation of further genetic results it was therefore necessary to ascertain the species identity of the specimens in our samples.

The new species *Horismenus butcheri* turned out to be important in understanding the impact of plant variability on the genetic structuring of parasitoid populations as it is the only species displaying plant-associated genetic differentiation and potential host-race formation (Aebi *et al*., unpublished data).

Beans are of great nutritional value in Central and South America. Bruchid beetles cause enormous economic losses to cultivated beans, 35% in Mexico and Central America, 7.4% in Colombia and 13% in Brazil (van Schoonhoven & Cardona 1986). As parasitoids of the genus *Horismenus* are the most abundant group in this system they might be good candidates for storage pest control. Indeed, several studies have documented the efficacy of endemic chalcidoid parasitoids in reducing storage bruchid infestations in Africa (Leveque *et al*. 1993; Sanon *et al*. 1998; Sanon *et al*. 1999; Van Huis *et al*. 2002). A recent study by Schmale *et al*. (2002) in Columbia showed that while *H. ashmeadii* Dalla Torre attacks bruchids (*A. obtectus*) in the field, it was unable to develop on bruchids under stored conditions (prior to this study the identity and nomenclature of some of the species included here has been very unclear and it is probable that the name *ashmeadii* has been wrongly interpreted in the past, see below “Remarks” under *H. productus*). However, we reared large numbers of *H. missouriensis* from cultivated beans collected on a monthly basis between December and February 2002 in various local markets. The continuance of parasitoid emergences during a period of 3 months confirmed that *H. missouriensis* can be successfully maintained under storage conditions. *H. missouriensis* was the only parasitoid reared from cultivated beans infested with the same bruchid genus as the wild beans. The fact that this parasitoid is also the most common *Horismenus* species found on wild bean samples, suggests that it most likely attacks cultivated beans in the field from where it gets transported by humans into storage facilities. The great species richness of this bruchid
Horismenus parasitoid complex highlights the importance of precise taxonomic identification of these and other beneficial insects for the success of biological control programs.

The genus Horismenus is predominantly a New World group, with its main distribution in the Neotropical region. Currently there are 53 species from the Americas (ten from the Nearctic, 39 from the Neotropics, and four from both regions), and one species from Europe. The species are parasitoids or hyperparasitoids on a variety of hosts, most commonly on larvae of Coleoptera, Diptera and Lepidoptera (LaSalle & Schauff 1995). Even though Horismenus is one of the most frequently encountered groups of Eulophidae in the Neotropical region very little is known of the genus from this biogeographical region. The majority of the species remain undescribed and the identities of many of the about 50 already described species are unclear due to poor original descriptions, missing type specimens, lack of revisions, etc.

FIGURE 1. Horismenus missouriensis, habitus, male.

Abbreviations of morphological terms

HE, height of eye; HW, height of forewing; LG, length of gaster; LM, length of marginal
vein in forewing; LW, length of forewing; MM, length of mesosoma; MS, length of malar space; OOL, shortest distance between one posterior ocellus and adjacent eye; PM, length of postmarginal vein in forewing; POL, distance between posterior ocelli; POO, distance between posterior ocelli and occipital margin; ST, length of stigmal vein in forewing; WH, width of head; WM, width of mouth opening; WT, width of thorax across “shoulders”. See Hansson (2002) for illustrations of these terms.

Acronyms of museums

Key to Horismenus species from Phaseolus spp. in Mexico

1 Scutellum flat, posteromedian part of scutellum smooth and shiny (Figs 12–13) ..........
   .................................................................................................. depressus Gahan (female, male)
   – Scutellum distinctly convex, posteromedian part of scutellum reticulate (Figs 4–5, 16–17)
     .......................................................................................................................... 2

2 Funicular segments longer (Figs 20–21), first funicular segment 3.5X as long as wide
   in female, 2.5–2.8X as long as wide in male; female gaster long, ratio length of meso-
   soma/length of gaster = 0.8–0.9 and with apex more pointed (Fig. 6) ......................
   ............................................................................................................. butcheri sp.nov. (female, male)
   – Funicular segments short and stout (Figs 24–26), female with first funicular segment
     at most 1.8X as long as wide, male with first funicular segment 1.9X as long as wide
     (appearance of flagellum in male productus not known); female gaster short, ratio
     length of mesosoma/length of gaster = 1.1–1.8 and with apex more rounded (Fig. 18)

3 Frons metallic bluish-green in female, metallic purple in male; female with first funi-
   cular segment 0.8X as long as second funicular segment (Fig. 24); female gaster longer
   than in alternate, ratio length of mesosoma/length of gaster = 1.1 .........................
   ............................................................................................................. missouriensis (Ashmead) (female, male)
   – Frons metallic purple in female, golden-green in male; female with first and second
     funicular segments equally long (Fig. 26); female gaster short, ratio length of meso-
     soma/length of gaster = 1.8.......................................................... productus (Ashmead) (female, male)
**Horismenus butcheri** sp. nov. Hansson & Aebi
Figs 2–7, 20–21

Diagnosis. Female gaster elongate (MM/LG = 0.8–0.9) (Fig. 6); female funicular segments long (Fig. 20), e.g. first funicular segment 3.5X as long as wide; male scape narrow, 4.5X as long as wide (Fig. 21).

Description. Length of body female 2.6–2.8 mm, male 2.2–2.6 mm.

Antennae as in Figs 20–21. Frons with strong small-meshed reticulation, reticulation weaker above frontal suture, interscrobal area and clypeal region smooth and shiny; frontal suture V-shaped, terminating before reaching eyes; antennal scrobes join below frontal suture. Vertex with strong, engraved and small-meshed reticulation; with a median groove in posterior half, groove continues down on occiput. Occipital margin rounded. Ratios of HE/MS/WM female 3.6/1.0/2.3, male 4.3/1.0/2.8; POL/OOL/POO 6.0/1.3/1.0; WH/WT 1.1.

Mesoscutum with strong large-meshed reticulation; notauli indistinct and wide in posterior 1/3. Scutellum with strong and engraved reticulation. Dorsellum smooth, with two large foveas anterolaterally, foveas reticulate. Coxae with weak reticulation. Fore wing speculum open below. Propodeum smooth and shiny, with sunken parts reticulate; propodeal callus with two setae. Petiole 1.1X as long as wide in female, 1.4X as long as wide in male. Ratios of LW/LM/HW 1.8/1.1/1.0; PM/ST 0.9.

First tergite smooth and shiny in anterior 1/3, posterior 2/3 with micropunctures. Ratios of MM/LG female 0.8–0.9, male 1.0–1.1.

Distribution. Mexico, USA (New Mexico).

Hosts. Acanthoscelides sp. on *Phaseolus vulgaris* L. and *Bruchus amicus* Horn, both hosts are Bruchidae (Coleoptera).

Material examined. Holotype female labeled “Mexico: Est. Mexico, Temascaltepec, 100°02´ W, 19°02´ N, 1750m, 21.xii.2001–2.iii.2002, A. Aebi, ex Acanthoscelides sp. on *Phaseolus vulgaris*” (BMNH). Paratypes: 3 females, 4 males with same label data as holotype (BMNH, USNM); 13 females 12 males from same locality as holotype but collected 5.i–20.ii.2003 (CH, CNIN, MHNN); 2 females, 1 male from same locality as holotype but collected 27.i–21.ii.2001 and from 1700m altitude (CNC); 3 females, 4 males from same locality as holotype but collected 16.xii.2001–3.ii.2002 and from 1700m altitude (BMNH, CNC); 5 females, 5 males “Mexico: Est. Mexico, Valle de Bravo, 100°09´ W, 18°56´ N,
1950m, 1.i–15.ii.2002, A. Aebi, ex Acanthoscelides sp. on Phaseolus vulgaris’” (CH, CNC, USNM). Non-type material: a female included in the type material of Horismenus productus (Ashmead) (see below) from Bruchus amicus in New Mexico (USNM) is conspecific with butcheri. This specimen is not included in the type material because it is damaged.

Etymology. This species is named in honour of Dr. Robert D.J. Butcher, for guidance and support throughout the dissertation research of Alexandre Aebi.

Horismenus depressus Gahan
Figs 8–13, 22–23

Horismenus depressus Gahan, 1930:8. Holotype female in USNM, not examined.

Diagnosis. Scutellum flat and with posteromedian part smooth and shiny (Figs 12–13); female gaster short (MM/LG = 1.1) and ovate (Fig. 8); female funicular segments short and stout (Fig. 22), e.g. first funicular segment 2.4X as long as wide; male scape 3.7X as long as wide (Fig. 23).

Description (of Mexican specimens). Length of body female 2.0–2.1 mm, male 1.9–2.0 mm.

Antennae as in Figs 22–23. Frons with strong small-meshed reticulation, reticulation weaker above frontal suture, interscrobal area smooth and shiny, clypeal region with weak transverse meshes; frontal suture V-shaped, terminating before reaching eyes; antennal scrobes join below frontal suture. Vertex with strong, engraved and small-meshed reticulation; with a median groove in posterior half, groove continues down on occiput. Occipital margin rounded. Ratios of HE/MS/WM female 3.6/1.0/2.2, male 3.2/1.0/2.0; POL/OOL/POO 5.7/1.3/1.0; WH/WT 1.1.

Mesoscutum with strong large-meshed reticulation; notauli indistinct and wide in posterior 1/3. Scutellum flat, with weak and engraved reticulation, partly to predominantly smooth. Dorsellum smooth, with two large foveae anterolaterally, foveae reticulate. Coxae smooth and shiny. Fore wing speculum open below. Propodeum smooth and shiny with sunken parts reticulate; propodeal callus with 2–3 setae. Petiole 1.1X as long as wide in female, 1.4X as long as wide in male. Ratios of LW/LM/HW 1.7/1.0/1.0; PM/ST 0.8.

First tergite smooth and shiny in anterior 1/3, posterior 2/3 with micropunctures. Ratios of MM/LG female 1.1, male 1.2.
Distribution. Mexico (De Santis 1989) and the U.S.A. (California (Gahan 1930), Texas (Burks 1971)).

Hosts. Acanthoscelides sp. on Phaseolus spp. (new record), A. obtectus (Say) (De Santis 1989), “Bruchus sp.” in Acacia seeds (Burks 1971), Stator pruininus (Horn) from seeds of Acacia and Olneya (Gahan 1930). All hosts are Bruchidae (Coleoptera).

Material examined. 22 females, 21 males from Mexico (Mexico, Michoacan, Morelos) from Acanthoscelides sp. on Phaseolus vulgaris (CH).

Horismenus missouriensis (Ashmead)
Figs 1, 14–19, 24–25

Horismenus missouriensis (Ashmead), Schmiedeknecht (1909).

Diagnosis. Female gaster short (MM/LG = 1.1) and ovate (Fig. 18); female funicular segments short and stout (Fig. 24), e.g. first funicular segment 1.7X as long as wide; male scape swollen (Fig. 25), 2.8X as long as wide.

Description (of Mexican specimens). Length of body female 2.2–2.5 mm, male 2.0–2.2 mm.

Antennae as in Figs 24–25. Frons with strong small-meshed reticulation, reticulation weaker above frontal suture, interscrobal area smooth and shiny, clypeal region with weak transverse meshes; frontal suture V-shaped and complete; antennal scrobes join below frontal suture. Vertex with weak, engraved and small-meshed reticulation; with a median groove in posterior half, groove continues down on occiput. Ocellar margin rounded. Ratios of HE/MS/WM female 4.2/1.0/2.5, male 2.9/1.0/2.4; POL/OOL/POO 3.2/1.0/1.0; WH/WT 1.0.

Mesoscutum with strong large-meshed reticulation; notauli distinct and more or less wide in posterior 1/3. Scutellum with strong and engraved reticulation. Dorsellum smooth, with two large foveae anterolaterally, foveae reticulate. Coxae predominantly smooth and shiny with very weak reticulation at base. Fore wing speculum open below. Propodeum smooth and shiny with sunken parts reticulate; propodeal callus with two setae. Petiole
1.1X as long as wide in female, 2.1X as long as wide in male. Ratios of LW/LM/HW 1.8/1.1/1.0; PM/ST 1.0.

First tergite smooth and shiny in anterior 1/3, posterior 2/3 micoreticulate with isodiametric meshes and with micropunctures, or predominantly with micropunctures. Ratios of MM/LG female 1.1, male 1.4.

Distribution. Brazil (De Santis 1980, Sari et al. 2002), Mexico (new record), U.S.A. (Ashmead 1888) (from New York and southward (Burks 1979)).

Hosts. Acanthoscelides sp. on Phaseolus spp. (new record), A. floridae Horn (Brett 1946), A. submuticus (Sharp) (Peck 1963), Amblycerus robiniae (Fabricius) (Peck 1951), Ctenocolum crotonae (Fähraeus) (Sari et al. 2002), Gibbobocharus sp. (Burks 1971). All hosts are Bruchidae (Coleoptera).

Material examined. 25 females, 21 males from Mexico (Distrito Federal, Mexico, Michoacan, Morelos) from Acanthoscelides sp./Zabrote sp. on Phaseolus vulgaris and P. coccineus (CH).

**Horismenus productus** (Ashmead)

Figs 26–29

*Holoceltel productus* Ashmead, 1894a:342. Lectotype female in USNM, here designated, examined.

*Horismenus productus* (Ashmead), Schmiedeknecht (1909).

Diagnosis. Female gaster short (MM/LG = 1.8) and round; female funicular segments short and stout (Fig. 26), e.g. first funicular segment 1.5X as long as wide; male scape swollen (Fig. 27), 3.2X as long as wide.

Description. Length of body female 1.8 mm, male 1.6 mm.

Female antenna as in Fig. 26, male scape as in Fig. 27 (flagellum missing in male antenna). Frons with strong small-meshed reticulation, reticulation weaker above frontal suture, interscrobal area and clypeal region smooth and shiny; frontal suture V-shaped and complete; antennal scrobes join below frontal suture. Vertex with weak small-meshed reticulation; with a median groove in posterior half, groove continues down on occiput. Occipital margin rounded. Ratios of HE/MS/WM female 3.1/1.0/1.8, male 3.8/1.0/2.2; POL/OOL/POO 2.3/1.0/1.3; WH/WT 1.2.

Mesoscutum with strong large-meshed reticulation. Scutellum with strong and engraved reticulation. Dorsellum smooth, with two large foveas anterolaterally. Coxae
predominantly smooth and shiny with very weak reticulation at base. Fore wing speculum open below. Propodeal callus with two setae. Ratios of LW/LM/HW 1.8/1.1/1.0; PM/ST 1.4.

First tergite smooth and shiny in anterior half, posterior half microreticulate with elongate meshes, remaining tergites hidden in first tergite. Ratios of MM/LG female 1.8, male 2.0.

Hosts. Bruchus amicus Horn (Ashmead 1894a). Host records published after the original description remain uncertain due to the difficulties of species identification and the confused nomenclature associated with this species.

Distribution. USA (New Mexico).

Material examined. Lectotype female “N. Mex.”, “Type No. 2144, U.S.N.M.” (USNM). Paralectotypes: 3 females, 1 male with same label data as lectotype (USNM). The lectotype and the paralectotypes are designated here (see below under “Remarks”).

Remarks. The type material of Horismenus productus Ashmead (1894a) consists of five specimens on three pins, two females, a male and a female, and a female. The single female, the male and the female on the same pin, and one of the females (the smaller female) on the pin with two females, are conspecific. The larger female on the pin with the two females belongs to a different species. The original description of productus is brief and not especially informative, but from the size range of the specimens given in the description (2–2.6 mm) it is obvious that productus was described from all specimens mentioned here. Possibly more specimens were included in the original description, specimens that subsequently have been lost – Ashmead states “several specimens” in the description. Since there are two species in the type material of productus, the question is which species shall bear the name “productus”. The description is of no help here so either one will do. We choose the species represented by most specimens, and also represented by both sexes, to carry the name productus. To maintain the nomenclatural stability we select the (smaller) female on the pin with the two females as lectotype for Horismenus productus. The large female on the same pin as the lectotype belongs to H. butcheri which is described above. The remaining type specimens mentioned here are designated as paralectotypes.

Ashmead described another species with the same name (productus), and during the same year (1894b), but this latter species was from St. Vincent. The “St. Vincent-species” has subsequently been renamed, “ashmeadii” (Dalla Torre 1898), and is not conspecific with productus from New Mexico (which retains the name productus). Both species were originally described in genus Holcopeselte, but both have subsequently been transferred to Horismenus.

The gastric tergites and sternites 2–7 have been retracted into the first tergite in all type specimens. The single male has lost the flagellum on both antennae.
