Minimality of toric arrangements

Giacomo d’Antonio Emanuele Delucchi

Abstract

We prove that the complement of a toric arrangement has the homotopy type of a minimal CW complex. As a corollary we obtain that the integer cohomology of these spaces is torsion free.

We use Discrete Morse Theory, providing a sequence of cellular collapses that leads to a minimal complex.

Keywords. Toric arrangements, Discrete Morse theory, Minimal CW complexes, Torsion in cohomology

Introduction

A toric arrangement is a finite family

$$\mathcal{A} = \{K_1, \ldots, K_n\}$$

of special subtori of the complex torus $\mathbb{C}^d$ (more precisely the $K_i$ are level sets of characters, see §2.1). Given a complexified toric arrangement $\mathcal{A}$ (see Definition 31) we consider the space

$$M(\mathcal{A}) := (\mathbb{C}^*)^d \setminus \bigcup \mathcal{A}$$

and prove that

(a) the space $M(\mathcal{A})$ is minimal in the sense of [14], i.e., it has the homotopy type of a CW complex with exactly $\beta_k = \text{rk } H^k(M(\mathcal{A}); \mathbb{Z})$ cells in dimension $k$, for every $k \in \mathbb{N}$, hence

(b) the space $M(\mathcal{A})$ is torsion-free, that is, the homology and cohomology modules $H_k(X; \mathbb{Z}), H^k(X; \mathbb{Z})$ are torsion free for every $k \in \mathbb{N}$.

The study of toric arrangements experienced a fresh impulse from recent work of De Concini, Procesi and Vergne [10, 9], in which toric arrangements emerge as a link between partition functions and box splines.

In their book [9], De Concini and Procesi emphasize some similarities between toric arrangements and the well-established theory of arrangements of affine hyperplanes. The present work provides substantial new evidence in this sense.

Mathematics Subject Classification (2010): 52B70, 52C35, 57Q05.
Background

Combinatorics. The combinatorial framework for the theory of arrangements of hyperplanes is widely considered to be given by matroid theory, a well-established branch of combinatorics that has proved very useful in this context ever since the seminal work of Zaslavsky [33].

The combinatorial study of toric arrangements has quite recent roots, and is still in search of a full-fledged pertaining theory. From an enumerative point of view, the arithmetic Tutte polynomial introduced by Moci in [23] summarizes previous results by Ehrenborg, Readdy and Slone [15] and of De Concini and Procesi [9]. This initiated the quest for a variation on the concept of matroid that would suit the ‘toric’ setting and lead D’Adderio and Moci [5] to suggest a theory of arithmetic matroids as a “combinatorialization” of the essential algebraic data of toric arrangements. Arithmetic matroids in fact encode - but, as yet, do not appear to characterize - some of the crucial combinatorial data of toric arrangements, for example the poset of layers (Definition 33). In this context, our work can be seen as exploration of the properties that would be required from a (still lacking) notion of a ‘toric oriented matroid’.

Topology. An important result in the theory of arrangements of hyperplanes was established by Brieskorn [3], who proved that the integer cohomology of the complement of an arrangement of complex hyperplanes is torsion-free. This allowed Orlik and Solomon to compute the integer cohomology algebra via the deRham complex [25]. Minimality of complements of complex hyperplane arrangements was proven much later by Randell in [27] and independently by Dimca and Papadima in [14], with Morse theoretic arguments. The explicit construction of such a minimal complex was studied by Yoshinaga [32], Salvetti and Settepanella [31] and the second author [12]. The present paper completes a similar circle of ideas for toric arrangements.

To our knowledge, the first result about the topology of toric arrangements was obtained by Looijenga [21] who deduced the Betti numbers of \( M(\mathcal{A}) \) from a spectral sequence computation. De Concini and Procesi in [8] expliclity expressed the generators of the cohomology modules over \( \mathbb{C} \) in terms of local no broken circuit sets and, for the special case of totally unimodular arrangements, were able to compute the cohomological algebra structure. A presentation of the fundamental group \( \pi_1(M(\mathcal{A})) \) of complexified toric arrangements was computed by the authors in [6], based on a combinatorially defined polyhedral complex carrying the homotopy type of the complement \( M(\mathcal{A}) \), called toric Salvetti complex. This polyhedral complex is given as the nerve of an acyclic category\(^2\) and was introduced by the authors in [6], generalizing to arbitrary complexified toric arrangements the complex defined by Moci and Settepanella in [24]. Recently, Davis and Settepanella [7] published vanishing results for cohomology of toric arrangements with coefficients in some particular local systems.

\(^2\)For our use of the term ‘acyclic category’ see Remark 23
Outline

Here we prove minimality by exhibiting, for a given complexified toric arrangement $\mathcal{A}$, a minimal CW-complex that is homotopy equivalent to $M(\mathcal{A})$. This complex is obtained from the toric Salvetti complex after a sequence of cellular collapses indexed by a discrete Morse function. The construction of the discrete Morse function relies on a stratification of the toric Salvetti complex where strata are counted by ‘local no-broken-circuit sets’ (Definition 39), which are known to control the Poincaré polynomial of $M(\mathcal{A})$ by [8].

The (topological) boundary maps of the minimal complex can be recovered in principle from the Discrete Morse data. The explicit computation of such boundary maps is in general difficult even in the case of hyperplane arrangements, where explicit computations are known only in dimension 2 either by following the discrete Morse gradient [17, 16] or by exploiting braid monodromy [18, 29, 30]. We leave the explicit computation of the boundary maps for our toric complex as a future direction of research.

As an application of our methods, in the last section we describe a construction of the minimal complex for complexified affine arrangements of hyperplanes that uses only the intrinsic combinatorics of the arrangement (i.e. its oriented matroid), as an alternative to the method of [31].

We close our introduction with a detailed outline of the paper.

- We begin with Section 1, where we review some known facts about the combinatorics and the topology of hyperplane arrangements and we prove some preparatory results about linear extensions of posets of regions of real arrangements.

- In Section 2 we give a short introduction to toric arrangements and we collect some results from the literature on which our work is built.

- Section 3 breaks the flow of material directly related to toric arrangements in order to develop Discrete Morse Theory for acyclic categories, generalizing the existing theory for posets.

- We approach the core of our work with Section 4, where we introduce a stratification and a related decomposition of the toric Salvetti complex (Definition 69).

- In order to understand the structure of the pieces of the decomposition of the toric Salvetti complex we need to patch together ‘local’ combinatorial data, which come from the theory of arrangements of hyperplanes. We do this in Section 5 using diagrams of acyclic categories.

- Our work culminates with Section 6. The keystone is Proposition 91, where we prove the existence of perfect acyclic matchings for the face categories of subdivisions of the compact torus given by toric arrangements. With this, we can apply the Patchwork Lemma of Discrete Morse Theory (in its version for acyclic categories) to our decomposition of the toric Salvetti complex to get an acyclic matching of the whole complex. This matching can be shown to be perfect and thus prescribes a series of cellular collapses leading to a minimal model for the complement of the toric arrangement.
As a further application of our methods, in Section 7 we show that our methods can be used to construct a minimal complex for the complement of (finite) complexified arrangements of hyperplanes.

1 Arrangements of hyperplanes

The theory of hyperplane arrangements is an important ingredient in our treatment of toric arrangements. In order to set the stage for the subsequent considerations, we therefore introduce the language and recall some relevant results about hyperplane arrangements. A standard reference for a comprehensive introduction to the subject is [26].

1.1 Generalities

Through this section let $V$ be a finite dimensional vector space over a field $\mathbb{K}$.

An affine hyperplane $H$ in $V$ is the level set of a linear functional on $V$. That is, there is $\alpha \in V^*$ and $a \in \mathbb{K}$ such that $H = \{v \in V \mid \alpha(v) = a\}$. A set of hyperplanes is called dependent or independent according to whether the corresponding set of elements of $V^*$ is dependent or not.

**Definition 1.** An arrangement of hyperplanes in $V$ is a collection $\mathcal{A}$ of affine hyperplanes in $V$.

An hyperplane arrangement $\mathcal{A}$ is called central if every hyperplane $H \in \mathcal{A}$ is a linear subspace of $V$; finite if $\mathcal{A}$ is finite; locally finite if for every $p \in V$ the set $\{H \in \mathcal{A} \mid p \in H\}$ is finite; real (or complex, or rational) if $V$ is a real (or complex, or rational) vector space.

When we will need to define a total order on the elements of a finite arrangement $\mathcal{A}$, we will do this by simply indexing the elements of $\mathcal{A}$, as $\mathcal{A} = \{H_1, \ldots, H_n\}$.

Much of the theory of hyperplane arrangements is devoted to the study of the complement of an arrangement $\mathcal{A}$. That is, the space

$$M(\mathcal{A}) := V \setminus \bigcup \mathcal{A}.$$  

**Definition 2.** Let $\mathcal{A}$ be an hyperplane arrangement, the intersection poset of $\mathcal{A}$ is the set

$$\mathcal{L}(\mathcal{A}) := \left\{ \bigcap \mathcal{K} \mid \mathcal{K} \subseteq \mathcal{A} \right\} \setminus \{\emptyset\}$$

of all nonempty intersections of elements of $\mathcal{A}$, ordered by reverse inclusion - i.e., for $X, Y \in \mathcal{L}(\mathcal{A})$, $X \succeq Y$ if $X \subseteq Y$.

Notice that the whole space $V$ is an element of $\mathcal{L}(\mathcal{A})$ (corresponding to the empty intersection), whereas the empty set is not. The intersection poset is a meet-semilattice and for central hyperplane arrangements is a lattice. Then, we speak of intersection lattice of $\mathcal{A}$. 
1.1.1 Deletion and restriction

Consider a hyperplane arrangement $\mathcal{A}$ in the vector space $V$ and an intersection $X \in \mathcal{L}(\mathcal{A})$. We associate to $X$ two new arrangements:

\[ \mathcal{A}_X = \{ H \in \mathcal{A} \mid X \subseteq H \}, \quad \mathcal{A}^X = \{ H \cap X \mid H \in \mathcal{A} \setminus \mathcal{A}_X \} .\]

Notice that $\mathcal{A}_X$ is an arrangement in $V$, while $\mathcal{A}^X$ is an arrangement on $X$.

**Remark 1.** If a total ordering $\mathcal{A} = \{ H_1, \ldots, H_n \}$ is defined, then it is clearly inherited by $\mathcal{A}_X$ for every $X \in \mathcal{L}(\mathcal{A})$. On the elements of $\mathcal{A}^X$ a total ordering is induced as follows. For $L \in \mathcal{A}^X$ define

\[ X_L := \min \{ H \in \mathcal{A} \mid L \subseteq H \} . \tag{1.1} \]

Then, order $\mathcal{A}^X := \{ L_1, \ldots, L_m \}$ so that, for all $1 \leq i < j \leq m$, $X_{L_i} < X_{L_j}$ in $\mathcal{A}$.

1.1.2 No Broken Circuit sets

In this section let $\mathcal{A}$ be a central hyperplane arrangement and fix an arbitrary total ordering of $\mathcal{A}$.

**Definition 3.** A circuit is a minimal dependent subset $C \subseteq \mathcal{A}$. A broken circuit is a subset of the form $C \setminus \{ \min C \} \subseteq \mathcal{A}$ obtained from a circuit removing its least element. A no broken circuit set (or, for short, an nbc set) is a subset $N \subseteq \mathcal{A}$ which does not contain any broken circuit.

**Remark 2.** An equivalent definition of nbc set is the following. A subset $N = \{ H_{i_1}, \ldots, H_{i_k} \} \subseteq \mathcal{A}$ with $i_1 \leq \cdots \leq i_k$ is a no broken circuit set if it is independent and there is no $j < i_1$ such that $N \cup \{ H_j \}$ is dependent.

**Definition 4.** We will write $\text{nbc}(\mathcal{A})$ for the set of no broken circuit sets of $\mathcal{A}$ and $\text{nbc}_k(\mathcal{A}) = \{ N \in \text{nbc}(\mathcal{A}) \mid |N| = k \}$ for the set of all no broken circuit sets of cardinality $k$.

1.2 Real arrangements

In this section we consider the case where $\mathcal{A}$ is an arrangement of hyperplanes in $\mathbb{R}^d$ in order to set up some notation and use the real structure to gain some deeper understanding in the combinatorics of no broken circuit sets.

It is not too difficult to verify that the complement $M(\mathcal{A})$ consists of several contractible connected components. These are called chambers of $\mathcal{A}$. We write $\mathcal{T}(\mathcal{A})$ for the set of all chambers of $\mathcal{A}$.

**Definition 5.** Let $\mathcal{A}$ a real arrangement, the set of faces of $\mathcal{A}$ is

\[ \mathcal{F}(\mathcal{A}) := \{ \text{relint}(\overline{C} \cap X) \mid C \in \mathcal{T}(\mathcal{A}), X \in \mathcal{L}(\mathcal{A}) \} . \]

We partially order this set by setting $F \leq G$ if $F \subseteq \overline{G}$ and call then $\mathcal{F}(\mathcal{A})$ the face poset of $\mathcal{A}$. 
Remark 3. A face $F \in \mathcal{F}(\mathcal{A})$ is an open subset of $\bigcap \{H \in \mathcal{A} \mid F \subseteq H\}$. By $\overline{F}$ we mean the topological closure of $F$ in $\mathbb{R}^d$.

Remark 4. Given $F \in \mathcal{F}(\mathcal{A})$ define the subarrangement $\mathcal{A}_F := \{H \in \mathcal{A} \mid F \subseteq H\}$. We have a natural poset isomorphism $\mathcal{F}(\mathcal{A}_F) \simeq \mathcal{F}(\mathcal{A})_{\geq F}$. Therefore, in the following we will identify these two posets.

One of the main enumerative questions about arrangements of hyperplanes in real space asks for the number of chambers of a given hyperplane arrangement. The answer is very elegant and somehow surprising.

Theorem 6 (Zaslavsky [33]). Given a real hyperplane arrangement $\mathcal{A}$,

$$|\mathcal{T}(\mathcal{A})| = |\text{nbc}(\mathcal{A})|.$$ 

1.2.1 Taking sides

If $\mathcal{A}$ is an arrangement in a real space $V$, then every hyperplane $H$ is the locus where a linear form $\alpha_H \in V^*$ takes the value $a_H$. This way we can associate to each $H \in \mathcal{A}$, its positive and negative halfspace:

$$H^+ = \{x \in V \mid \alpha_H(x) > a_H\}, \quad H^- = \{x \in V \mid \alpha_H(x) < a_H\}.$$ 

Definition 7. Consider a complexified locally finite arrangement $\mathcal{A}$ with any choice of ‘sides’ $H^+$ and $H^-$ for every $H \in \mathcal{A}$. The sign vector of a face $F \in \mathcal{F}(\mathcal{A})$ is the function $\gamma_F : \mathcal{A} \to \{-, +\}$ defined as:

$$\gamma_F(H) := \begin{cases} + & \text{if } F \subseteq H^+, \\ 0 & \text{if } F \subseteq H, \\ - & \text{if } F \subseteq H^-. \end{cases}$$

When we will need to specify the arrangement $\mathcal{A}$ to which the sign vector refers, we will write $\gamma[\mathcal{A}]_F(H)$ for $\gamma_F(H)$.

Remark 5. The poset $\mathcal{F}(\mathcal{A})$ is isomorphic to the set $\{\gamma_F \mid F \in \mathcal{F}(\mathcal{A})\}$ with partial order given by $\gamma_F \leq \gamma_G$ if $\gamma_F(H) = \gamma_G(H)$ whenever $\gamma_G(H) \neq 0$ (see e.g. [2]).

Definition 8. Let $C_1$ and $C_2 \in \mathcal{T}(\mathcal{A})$ be chambers of a real arrangement, and let $B \in \mathcal{T}(\mathcal{A})$ be a distinguished chamber. We will write

$$S(C_1, C_2) := \{H \in \mathcal{A} \mid \gamma_{C_1}(H) \neq \gamma_{C_2}(H)\}$$

for the set of hyperplanes of $\mathcal{A}$ which separate $C_1$ and $C_2$. For all $C_1, C_2 \in \mathcal{T}(\mathcal{A})$ write

$$C_1 \leq C_2 \iff S(C_1, B) \subseteq S(C_2, B).$$

This turns $\mathcal{T}(\mathcal{A})$ into a poset $\mathcal{T}(\mathcal{A})_B$, the poset of regions of the arrangement $\mathcal{A}$ with base chamber $B$. 

http://doc.rero.ch
Remark 6. Let $\mathcal{A}_0$ be a real arrangement and $B \in \mathcal{T}(\mathcal{A}_0)$. Given a subarrangement $\mathcal{A}_1 \subseteq \mathcal{A}_0$, for every chamber $C \in \mathcal{T}(\mathcal{A}_0)$ there is a unique chamber $\widehat{C} \in \mathcal{T}(\mathcal{A}_1)$ with $C \subseteq \widehat{C}$. The correspondence $C \mapsto \widehat{C}$ defines a surjective map
\[ \sigma_{\mathcal{A}_1} : \mathcal{T}(\mathcal{A}_0)_B \to \mathcal{T}(\mathcal{A}_1)_{\widehat{B}} \]
such that $C \leq C'$ implies $\sigma_{\mathcal{A}_1}(C') \leq \sigma_{\mathcal{A}_1}(C''')$ for all $C, C'' \in \mathcal{T}(\mathcal{A}_0)$.

Definition 9. Let $\mathcal{A}_0$ be a real arrangement and let $\succ_0$ denote any total ordering of $\mathcal{T}(\mathcal{A}_0)$. Consider a subarrangement $\mathcal{A}_1 \subseteq \mathcal{A}_0$. The section
\[ \mu[\mathcal{A}_1, \mathcal{A}_0] : \mathcal{T}(\mathcal{A}_1) \to \mathcal{T}(\mathcal{A}_0), \quad C \mapsto \min\{K \in \mathcal{T}(\mathcal{A}_0) \mid K \subseteq C\} \]
of $\sigma_{\mathcal{A}_1}$ defines a total ordering $\succ_{0,1}$ on $\mathcal{T}(\mathcal{A}_1)$ by
\[ C \succ_{0,1} D \iff \mu[\mathcal{A}_1, \mathcal{A}_0](C) \succ_0 \mu[\mathcal{A}_1, \mathcal{A}_0](D) \]
that we call \textit{induced by} $\succ_0$.

Lemma 10. Consider real arrangements $\mathcal{A}_2 \subseteq \mathcal{A}_1 \subseteq \mathcal{A}_0$, a given total ordering $\succ_0$ of $\mathcal{T}(\mathcal{A}_0)$ and the induced total ordering $\succ_{0,1}$ of $\mathcal{T}(\mathcal{A}_1)$. Then
\[ \mu[\mathcal{A}_1, \mathcal{A}_0] \circ \mu[\mathcal{A}_2, \mathcal{A}_1] = \mu[\mathcal{A}_2, \mathcal{A}_0]. \]

Proof. Take any $C \in \mathcal{T}(\mathcal{A}_2)$ and define
\[ C_0 := \mu[\mathcal{A}_2, \mathcal{A}_0](C); \quad C_1 := \sigma_{\mathcal{A}_1}(C_0), \quad \text{so } \mu[\mathcal{A}_1, \mathcal{A}_0](C_1) = C_0; \]
\[ C_2 := \mu[\mathcal{A}_2, \mathcal{A}_1](C); \quad C_3 := \mu[\mathcal{A}_1, \mathcal{A}_0](C_2). \]
we have to show that $C_0 = C_3$.
First, notice that $C_0 \preceq_0 C_3$ because $C_3 \subseteq C_2 \subseteq C$. For the reverse inequality notice that we have $C_1, C_2 \subseteq C$, which implies $C_2 \preceq_{0,1} C_1$ and so, by definition of the induced ordering, $C_3 = \mu[\mathcal{A}_1, \mathcal{A}_0](C_2) \preceq_0 \mu[\mathcal{A}_1, \mathcal{A}_0](C_1) = C_0$. \hfill \square

Proposition 11. Let a base chamber $B$ of $\mathcal{A}_0$ be chosen. If $\succ_0$ is a linear extension of $\mathcal{T}(\mathcal{A}_0)_B$, then $\succ_{0,1}$ is a linear extension of $\mathcal{T}(\mathcal{A}_1)_{\widehat{B}}$.

Proof. We have to prove that for all $C, D \in \mathcal{T}(\mathcal{A}_1)$, $C \preceq D$ in $\mathcal{T}(\mathcal{A}_1)_{\widehat{B}}$ implies $C \preceq_{0,1} D$, i.e., $\mu[\mathcal{A}_0, \mathcal{A}_1](C) \preceq_0 \mu[\mathcal{A}_0, \mathcal{A}_1](D)$.
We argue by induction on $k := |\mathcal{A}_0 \setminus \mathcal{A}_1|$, the claim being evident when $k = 0$. Suppose then that $k > 0$, choose $H \in \mathcal{A}_0 \setminus \mathcal{A}_1$ and set $\mathcal{A}_0' := \mathcal{A}_0 \setminus \{H\}$. By induction hypothesis we have
\[ \mu[\mathcal{A}_0', \mathcal{A}_1](C) \preceq_0 \mu[\mathcal{A}_0', \mathcal{A}_1](D), \]
which by definition means
\[ \mu[\mathcal{A}_0, \mathcal{A}_1'](\mu[\mathcal{A}_0', \mathcal{A}_1](C)) \preceq_0 \mu[\mathcal{A}_0, \mathcal{A}_1'](\mu[\mathcal{A}_0', \mathcal{A}_1](D)) \]
and thus, via Lemma 10, $\mu[\mathcal{A}_0, \mathcal{A}_1](C) \preceq_0 \mu[\mathcal{A}_0, \mathcal{A}_1](D)$. \hfill \square
1.3 Complex(ified) arrangements

We turn to the case of complex hyperplane arrangements, where the space $M(\mathcal{A})$ has subtler topology. For the sake of concision here we deliberately disregard the chronological order in which the relevant theorems were proved, and start with the minimality result.

**Definition 12.** Let $X$ be a topological space. For $j \geq 0$, the $j$-th Betti number is $\beta_j(X) := \text{rk } H^j(M(\mathcal{A})), \mathbb{Z})$. The space $X$ is called minimal if it is homotopy equivalent to a CW-complex with $\beta_j(X)$ cells of dimension $j$, for all $j \geq 0$. Such a CW-complex is also called minimal.

**Theorem 13** (Randell [27], Dimca and Papadima [14]). The space $M(\mathcal{A})$ is minimal.

**Corollary 14.** The cohomology groups $H^k(M(\mathcal{A}), \mathbb{Z})$ are torsion-free.

**Proof.** Theorem 13 asserts the existence of a minimal complex for $M(\mathcal{A})$. The (algebraic) boundary maps of the chain complex constructed from this minimal complex are all zero, thus torsion cannot arise in homology.

Corollary 14 can be traced back to the seminal work of Brieskorn [3], where also the following other important fact about the cohomology of affine arrangements of hyperplanes was proved.

**Theorem 15** (Brieskorn [3]). Let $\mathcal{A}$ be a finite affine hyperplane arrangement. Then, for every $p \in \mathbb{N}$

$$H^p(M(\mathcal{A}); \mathbb{Z}) \cong \bigoplus_{X \in L(\mathcal{A})_p} H^p(M(\mathcal{A}_X); \mathbb{Z}),$$

where $L(\mathcal{A})_p = \{X \in L(\mathcal{A}) \mid \text{codim}(X) = p\}$.

Intimely related with this torsion-freeness is the fact that it is enough to compute de Rham cohomology in order to know the cohomology with integer coefficients, the so-called *Orlik-Solomon algebra* introduced in [25]. Here, too, no broken circuit sets enter the picture as most handy combinatorial invariants.

**Theorem 16.** Let $\mathcal{A}$ be a complex central hyperplane arrangement, then the Poincaré polynomial of $M(\mathcal{A})$ satisfies

$$P_{\mathcal{A}}(t) := \sum_{j \geq 0} \text{rk } H^j(M(\mathcal{A}); \mathbb{Z}) t^j = \sum_{j \geq 0} \text{nb}_{\mathcal{A}} t^j.$$

**Remark 7.** In particular, the numbers $|\text{nb}_{\mathcal{A}}|$ do not depend on the chosen ordering of $\mathcal{A}$.

**Remark 8** ([19]). Combining Theorem 15 with Theorem 16 we get the following formula for the Poincaré polynomial of the complement of an arbitrary finite affine complex arrangement:

$$P_{\mathcal{A}}(t) := \sum_{X \in L(\mathcal{A})} |\text{nb}_{\mathcal{A}} X(\mathcal{A}_X)| t^\text{codim } X.$$
We now turn to a special class of arrangements in complex space.

**Definition 17.** An arrangement $\mathcal{A}$ in $\mathbb{C}^d$ is called *complexified* if every hyperplane $H \in \mathcal{A}$ is the complexification of a real hyperplane, i.e. if there is $\alpha_H \in (\mathbb{R}^d)^*$ and $a_H \in \mathbb{R}$ with

$$H = \{ x \in \mathbb{C}^d \mid \alpha_H(\Re(x)) + i\alpha_H(\Im(x)) = a_H \}.$$

Let $\mathcal{A}$ be a complexified arrangement and consider its real part $\mathcal{A}_R = \{ H \cap \mathbb{R}^d \mid H \in \mathcal{A} \}$, an arrangement of hyperplanes in $\mathbb{R}^d$. Notice that $L(\mathcal{A}) \cong L(\mathcal{A}_R)$ and therefore $\text{nbc}(\mathcal{A}) = \text{nbc}(\mathcal{A}_R)$.

If $\mathcal{A}$ is a complexified arrangement, one can use the combinatorial structure of $\mathcal{A}_R$ to study the topology of $M(\mathcal{A})$. Therefore we will write $\mathcal{F}(\mathcal{A}) = \mathcal{F}(\mathcal{A}_R)$, $\mathcal{T}(\mathcal{A}) = \mathcal{T}(\mathcal{A}_R)$.

### 1.3.1 The homotopy type of complexified arrangements

Using combinatorial data about $\mathcal{A}_R$, Salvetti defined in [28] a cell complex which embeds in the complement $M(\mathcal{A})$ as a deformation retract. We explain Salvetti’s construction.

**Definition 18.** Given a face $F \in \mathcal{F}(\mathcal{A})$ and a chamber $C \in \mathcal{T}(\mathcal{A})$, define $C_F \in \mathcal{T}(\mathcal{A})$ as the unique chamber such that, for $H \in \mathcal{A}$,

$$\gamma_{C_F}(H) = \begin{cases} \gamma_F(H) & \text{if } \gamma_F(H) \neq 0, \\ \gamma_C(H) & \text{if } \gamma_F(H) = 0. \end{cases}$$

The reader may think of $C_F$ as the one, among the chambers adjacent to $F$, that “faces” $C$.

**Definition 19.** Consider an affine complexified locally finite arrangement $\mathcal{A}$ and define the *Salvetti poset* as follows:

$$\text{Sal}(\mathcal{A}) = \{ [F, C] \mid F \in \mathcal{F}(\mathcal{A}), C \in \mathcal{T}(\mathcal{A}) F \leq C \},$$

with the order relation

$$[F_1, C_1] \leq [F_2, C_2] \iff F_2 \leq F_1 \text{ and } (C_2)_{F_1} = C_1.$$

**Definition 20.** Let $\mathcal{A}$ be an affine complexified locally finite hyperplane arrangement. Its *Salvetti complex* is $S(\mathcal{A}) = \Delta(\text{Sal}(\mathcal{A}))$.

**Theorem 21** (Salvetti [28]). The complex $S(\mathcal{A})$ is homotopically equivalent to the complement $M(\mathcal{A})$. More precisely $S(\mathcal{A})$ embeds in $M(\mathcal{A})$ as a deformation retract.

**Remark 9.** In fact, the poset $\text{Sal}(\mathcal{A})$ is the face poset of a regular cell complex (of which $S(\mathcal{A})$ is the barycentric subdivision) whose maximal cells correspond to the pairs

$$\{ [P, C] \mid P \in \text{min} \mathcal{F}(\mathcal{A}), C \in \mathcal{T}(\mathcal{A}) \}.$$

It is this complex that Salvetti describes in [28]. When we need to distinguish between the two complexes we will speak of *cellular* and *simplicial* Salvetti complex.
1.3.2 Minimality

In the case of complexified arrangements, explicit constructions of a minimal CW-complex for $M(\mathcal{A})$ were given in [31] and in [12]. We review the material of [12, §4] that will be useful for our later purposes.

Lemma 22 ([12, Theorem 4.13]). Let $\mathcal{A}$ be a central arrangement of real hyperplanes, let $B \in \mathcal{T}(\mathcal{A})$ and let $\preceq$ be any linear extension of the poset $\mathcal{T}(\mathcal{A})_B$. The subset of $L(\mathcal{A})$ given by all intersections $X$ such that $S(C, C') \cap X \neq \emptyset$ for all $C' \prec C$ is an order ideal of $L(\mathcal{A})$. In particular, it has a well defined and unique minimal element we will call $X_C$.

Remark 10. Note that $X_C$ depends on the choice of $B$ and of the linear extension of $\mathcal{T}(\mathcal{A})_B$.

Corollary 23. For all $C \in \mathcal{T}(\mathcal{A})$ we have

$$C = \min_{\preceq} \{ K \in \mathcal{T}(\mathcal{A}) \mid K_{X_C} = C_{X_C} \},$$

where, for $Y \in L(\mathcal{A})$ and $K \in \mathcal{T}(\mathcal{A})$, we define $K_Y := \sigma_{\mathcal{A}_Y}(K)$.

Now recall the (cellular) Salvetti complex of Definition 20 and Remark 9. In particular, its maximal cells correspond to the pairs $[P, C]$ where $P$ is a point and $C$ is a chamber. When $\mathcal{A}$ is a central arrangement, the maximal cells correspond to the chambers in $\mathcal{T}(\mathcal{A})$. In this case we can stratify the Salvetti complex assigning to each chamber $C \in \mathcal{T}(\mathcal{A})$ the corresponding maximal cell of $S(\mathcal{A})$, together with its faces. Let us make this precise.

Definition 24. Let $\mathcal{A}$ be a central complexified hyperplane arrangement and write $\min F(\mathcal{A}) = \{ P \}$. Define a stratification of the cellular Salvetti complex $S(\mathcal{A}) = \bigcup_{C \in \mathcal{T}(\mathcal{A})} S_C$ through

$$S_C := \bigcup \{ [F, K] \in \text{Sal}(\mathcal{A}) \mid [F, K] \preceq [P, C] \}.$$

Given an arbitrary linear extension $(\mathcal{T}(\mathcal{A}), \preceq)$ of $\mathcal{T}(\mathcal{A})_B$, for all $C \in \mathcal{T}(\mathcal{A})$ define

$$\mathcal{N}_C := S_C \setminus \left( \bigcup_{D \prec C} S_D \right).$$

In particular the poset $\text{Sal}(\mathcal{A})$ can be partitioned as

$$\text{Sal}(\mathcal{A}) = \bigsqcup_{C \in \mathcal{T}(\mathcal{A})} \mathcal{N}_C(\mathcal{A}).$$

Theorem 25 ([12, Lemma 4.18]). There is an isomorphism of posets

$$\mathcal{N}_C \cong F(\mathcal{A}_{X_C})^{op}$$

where $X_C$ is the intersection defined via Lemma 22 by the same choice of base chamber and of linear extension of $\mathcal{T}(\mathcal{A})_B$ used to define the subposets $\mathcal{N}_C$. 
Remark 11. The alternative proof given in [12] of minimality of $M(\mathcal{A})$ for $\mathcal{A}$ a complexified central arrangement follows from Theorem 25 by an application of Discrete Morse Theory (see Section 3). Indeed, from a shelling order of $\mathcal{F}(\mathcal{A}^{X_c})$ one can construct a sequence of cellular collapses of the induced subcomplex of $S_C$ that leaves only one ‘surviving’ cell. Via the Patchwork Lemma (Lemma 52 below) these sequences of collapses can be concatenated to give a sequence of collapses on the cell complex $S(\mathcal{A})$. The resulting complex after the collapses has one cell for every $N_C$, namely $|\text{nbc}(A)| = P_A(1)$ cells, and is thus minimal.

Example 26. Consider the arrangement of Figure 1. We have

$$L(\mathcal{A}) = \{\mathbb{R}^2, H_1, H_2, H_3, P\}$$

where $P = H_1 \cap H_2 \cap H_3$. The chambers are ordered according to their indices, $B$ being the base chamber. Then, $X_B = \mathbb{R}^2$, $X_{C_1} = H_3$, $X_{C_2} = H_1$, $X_{C_3} = H_2$, $X_{C_4} = X_{C_5} = P$.

Recall the construction of the cellular Salvetti Complex (e.g. from [6, Definition 2.4]). Figure 1.(a) shows the stratum $S_B = \mathcal{N}_B$ (dotted shading) and the stratum $\mathcal{N}_{C_1}$ (solid...
shading). The stratum $\mathcal{N}_{C_1}$ consists of two 1-dimensional faces and one 2-dimensional face. Its poset structure is showed in Figure 1.(c) and it is isomorphic, as a poset, to the order dual of $\mathcal{F}(\mathcal{N}_{C_1})$, depicted in Figure 1.(b).

2 Toric arrangements

2.1 Introduction

We have presented arrangements of hyperplanes in affine space as families of level sets of linear forms. Now, we want to explain in which sense this idea generalizes to a toric setting.

Our ambient spaces will be the complex torus $(\mathbb{C}^*)^d$ and the compact (or real) torus $(S^1)^d$, where we consider $S^1$ as the unit circle in $\mathbb{C}$. We consider characters of the torus, i.e., maps $\chi : (\mathbb{C}^*)^d \to \mathbb{C}^*$ given by

$$\chi(x_1, \ldots, x_d) = x_1^{\alpha_1} x_2^{\alpha_2} \cdots x_d^{\alpha_d} \text{ for an } \alpha = (\alpha_1, \ldots, \alpha_d) \in \mathbb{Z}^d.$$  

Characters form a lattice, which we denote by $\Lambda$, under pointwise multiplication. Notice that the assignment $\alpha \mapsto x_1^{\alpha_1} \cdots x_d^{\alpha_d}$ provides an isomorphism $\mathbb{Z}^d \to \Lambda$.

We consider subtori defined as level sets of characters, that is hypersurfaces in $(\mathbb{C}^*)^d$ of the form

$$K = \{ x \in (\mathbb{C}^*)^d \mid \chi(x) = a \} \text{ with } \chi \in \Lambda, a \in \mathbb{C}^*. \quad (2.1)$$

Notice that, if $a \in S^1$, the intersection $K \cap (S^1)^d$ is also a level set of a character (described by the same equation).

**Definition 27.** A (complex) toric arrangement $\mathcal{A}$ in $(\mathbb{C}^*)^d$ is a finite set

$$\mathcal{A} = \{ K_1, \ldots, K_n \}$$

of hypersurfaces of the form (2.1) in $(\mathbb{C}^*)^d$

**Definition 28.** Let $\mathcal{A}$ be a toric arrangement in $(\mathbb{C}^*)^d$. Its complement is

$$M(\mathcal{A}) := (\mathbb{C}^*)^d \setminus \bigcup \mathcal{A}.$$  

**Definition 29.** A real toric arrangement $\mathcal{A}$ in $(S^1)^d$ is a finite set

$$\mathcal{A}^c = \{ K_1^c, \ldots, K_n^c \}$$

of hypersurfaces $K_i^c$ in $(S^1)^d$ of the form (2.1) with $a \in S^1$. If a complex toric arrangement restricts to a real toric arrangement on $(S^1)^d$ we will call $\mathcal{A}$ complexified.

We will often use this interplay between the complex and the ‘real’ hypersurfaces in the same vein that one exploits properties of the real part of complexified arrangements to gain insight into the complexification.
2.2 An abstract approach

We now introduce an equivalent but more abstract approach to toric arrangements. Being able to switch point of view according to the situation will make our considerations below considerably more transparent.

**Definition 30.** Let \( \Lambda \cong \mathbb{Z}^d \) a finite rank lattice. The corresponding **complex torus** is

\[
T_\Lambda = \text{hom}_{\mathbb{Z}}(\Lambda, \mathbb{C}^*)
\]

The **compact (or real) torus** corresponding to \( \Lambda \) is

\[
T^c_\Lambda = \text{hom}_{\mathbb{Z}}(\Lambda, S^1),
\]

where, again, \( S^1 := \{ z \in \mathbb{C} \mid |z| = 1 \} \).

The choice of a basis \( \{ u_1, \ldots, u_d \} \) of \( \Lambda \) gives isomorphisms

\[
\Phi : T_\Lambda \rightarrow (\mathbb{C}^*)^d \quad \Phi^c : T^c_\Lambda \rightarrow (S^1)^d
\]

\[
\varphi \mapsto (\varphi(u_1), \ldots, \varphi(u_d)) \quad \varphi \mapsto (\varphi(u_1), \ldots, \varphi(u_d))
\]

(2.2)

**Remark 12.** Consider a finite rank lattice \( \Lambda \) and the corresponding torus \( T_\Lambda \). The **characters** of \( T_\Lambda \) are the functions

\[
\chi_\lambda : T_\Lambda \rightarrow \mathbb{C}^*, \quad \chi_\lambda(\varphi) = \varphi(\lambda) \text{ with } \lambda \in \Lambda.
\]

Characters form a lattice under pointwise multiplication, and this lattice is naturally isomorphic to \( \Lambda \). Therefore in the following we will identify the character lattice of \( T_\Lambda \) with \( \Lambda \).

Now, the ‘abstract’ definition of toric arrangements is the following.

**Definition 31.** Consider a finite rank lattice \( \Lambda \), a **toric arrangement** in \( T_\Lambda \) is a finite set of pairs

\[
\mathcal{A} = \{(\chi_1, a_1), \ldots, (\chi_n, a_n)\} \subset \Lambda \times \mathbb{C}^*.
\]

A toric arrangement \( \mathcal{A} \) is called **complexified** if \( \mathcal{A} \subset \Lambda \times S^1 \).

**Remark 13.** The abstract definition is clearly equivalent to Definition 29 via the isomorphisms in (2.2) and by

\[
K_i := \{ x \in T_\Lambda \mid \chi_i(x) = a_i \}.
\]

(2.3)

Accordingly, we have \( M(\mathcal{A}) := T_\Lambda \setminus \bigcup K_1, \ldots, K_n \).

**Definition 32.** Let \( \Lambda \) be a finite rank lattice. A **real** toric arrangement in \( T^c_\Lambda \) is a finite set of pairs

\[
\mathcal{A}^c = \{(\chi_1, a_1), \ldots, (\chi_n, a_n)\} \subset \Lambda \times S^1.
\]

**Remark 14.** A complexified toric arrangement \( \mathcal{A} \) in \( T_\Lambda \) induces a real toric arrangement \( \mathcal{A}^c \) in \( T^c_\Lambda \) with

\[
K_i^c := \{ x \in T^c_\Lambda \mid \chi_i(x) = a_i \}.
\]

Furthermore, embedding \( T^c_\Lambda \hookrightarrow T_\Lambda \) in the obvious way, we have \( K_i^c = K_i \cap T^c_\Lambda \) as in Definition 29.
We now illustrate what has been proposed [8, 22] as the ‘toric analogue’ of the intersection poset (see Definition 2).

**Definition 33.** Let $\mathcal{A} = \{(\chi_1, a_1), \ldots, (\chi_n, a_n)\}$ be a toric arrangement on $T_\Lambda$. A layer of $\mathcal{A}$ is a connected component of a nonempty intersection of some of the subtori $K_i$ (defined in Remark 13). The set of all layers of $\mathcal{A}$ ordered by reverse inclusion is the poset of layers of the toric arrangement, denoted by $\mathcal{C}(\mathcal{A})$.

Notice that, as in the case of hyperplane arrangements, the torus $T_\Lambda$ itself is a layer, while the empty set is not.

**Definition 34.** Let $\Lambda$ be a rank $d$ lattice and let $\mathcal{A}$ be a toric arrangement on $T_\Lambda$. The rank of $\mathcal{A}$ is $\text{rk}(\mathcal{A}) := \text{rk} \langle \chi \mid (\chi, a) \in \mathcal{A} \rangle$.

(a) A character $\chi \in \Lambda$ is called primitive if, for all $\psi \in \Lambda$, $\chi = \psi^k$ only if $k \in \{-1, 1\}$.

(b) The toric arrangement $\mathcal{A}$ is called primitive if for each $(\chi, a) \in \mathcal{A}$, $\chi$ is primitive.

(c) The toric arrangement $\mathcal{A}$ is called essential if $\text{rk}(\mathcal{A}) = d$.

**Remark 15.** For every non primitive arrangement there is a primitive arrangement which has the same complement. Furthermore, if $\mathcal{A}$ is a non essential arrangement, then there is an essential arrangement $\mathcal{A}'$ such that

$$M(\mathcal{A}) \cong (\mathbb{C}^*)^{d-l} \times M(\mathcal{A}')$$

where $l = \text{rk}(\mathcal{A}')$.

Therefore the topology of $M(\mathcal{A})$ can be derived from the topology of $M(\mathcal{A}')$.

In view of Remark 15, our study of the topology of complements of toric arrangements will not loose in generality by stipulating the next assumption.

**Assumption 35.** From now on we assume every toric arrangement to be primitive and essential.

### 2.2.1 Deletion and restriction

Let $\Lambda$ be a finite rank lattice and $\mathcal{A}$ be a toric arrangement in $T_\Lambda$.

**Definition 36.** For every sublattice $\Gamma \subseteq \Lambda$ we define the arrangement

$$\mathcal{A}_\Gamma = \{(\chi, a) \mid \chi \in \Gamma\},$$

for every layer $X \in \mathcal{C}(\mathcal{A})$ a sublattice

$$\Gamma_X := \{\chi \in \Lambda \mid \chi \text{ is constant on } X\} \subseteq \Lambda.$$

**Definition 37.** Let $X$ be a layer of $\mathcal{A}$. We define toric arrangements

$$\mathcal{A}_X := \mathcal{A}_{\Gamma_X} \text{ on } T_{\Gamma_X},$$

and

$$\mathcal{A}^X := \{K_i \cap X \mid X \not\subseteq K_i\} \text{ on the torus } X.$$
Remark 16. Notice that for a layer $X \in \mathcal{C}(\mathcal{A})$ and an hypersurface $K$ of $\mathcal{A}$, the intersection $K \cap X$ needs not to be connected.

In general $K \cap X$ consist of several connected components, each of which is a level set of a character in the torus $X$. In particular $\mathcal{A}^X$ is a toric arrangement in the sense of Definition 31.

2.2.2 Covering space

We now recall a construction of [6] which we need in the following. For more details we refer to [6, §3.2]. Consider the covering map:

$$p : \mathbb{C}^d \cong \text{Hom}_\mathbb{Z}(\Lambda; \mathbb{C}) \to \text{Hom}_\mathbb{Z}(\Lambda; \mathbb{C}^*) = T_\Lambda$$

$$\varphi \mapsto \exp \circ \varphi$$

(2.4)

Notice that identifying $\text{Hom}_\mathbb{Z}(\Lambda, \mathbb{C}) \cong \mathbb{C}^d$, $p$ becomes the universal covering map

$$(t_1, \ldots, t_d) \mapsto (e^{2\pi it_1}, \ldots, e^{2\pi it_d})$$

of the torus $T_\Lambda$. Also, this map restricts to a universal covering map

$$\mathbb{R}^d \cong \text{Hom}_\mathbb{Z}(\Lambda; \mathbb{R}) \to \text{Hom}_\mathbb{Z}(\Lambda, S^1) \cong (S^1)^d.$$ 

Consider now a toric arrangement $\mathcal{A}$ on $T_\Lambda$. Its preimage through $p$ is a locally finite affine hyperplane arrangement on $\text{Hom}_\mathbb{Z}(\Lambda; \mathbb{C})$

$$\mathcal{A}^\Lambda = \{(\chi, a') \in \Lambda \times \mathbb{C} \mid (\chi, e^{2\pi ia'}) \in \mathcal{A}\}.$$ 

If we write it in coordinates, $\mathcal{A}^\Lambda$ becomes the arrangement on $\mathbb{C}^d$ defined as

$$\mathcal{A}^\Lambda = \{H_{\chi, a'} \mid (\chi, e^{2\pi ia'}) \in \mathcal{A}\} \text{ with } H_{\chi, a'} = \{x \in \mathbb{C}^n \mid \sum \alpha_i x_i = a'\},$$ 

where we expanded $\chi(x) = x_1^{\alpha_1} \cdots x_d^{\alpha_d}$.

Remark 17. If the toric arrangement $\mathcal{A}$ is complexified, so is the hyperplane arrangement $\mathcal{A}^\Lambda$.

2.3 Combinatorics

As in the case of hyperplanes, one would like to describe the topology of the complement in terms of the combinatorics of the arrangement.

Lemma 38. Let $\mathcal{A}$ be a toric arrangement, $X \in \mathcal{C}(\mathcal{A})$ a layer. Then the subposet $\mathcal{C}(\mathcal{A}) \leq X$ is the intersection poset of a central hyperplane arrangement $\mathcal{A}[X]$. If $\mathcal{A}$ is complexified, then $\mathcal{A}[X]$ is, too.

Proof. This is implicit in much of [8, 22], the proof follows by lifting the layer $X$ to $\mathcal{A}^\Lambda$. A formally precise definition of $\mathcal{A}[Y]$ can also be found in Section 4.1 below. \qed
In other words, lower intervals of posets of layers are intersection lattices of (central)
hyperplane arrangements. The following definition is then natural.

**Definition 39** ([8, 22]). Let $\mathcal{A}$ be a toric arrangement of rank $d$ and let us fix a total
ordering on $\mathcal{A}$. A *local no broken circuit set* of $\mathcal{A}$ is a pair

$$(X, N) \text{ with } X \in \mathcal{C}(\mathcal{A}), N \in \text{nbck}(\mathcal{A}(X)) \text{ where } k = d - \dim X$$

We will write $\mathcal{N}$ for the set of local non broken circuits, and partition it into subsets

$$\mathcal{N}_j = \{(X, N) \in \mathcal{N} \mid \dim X = d - j\}.$$  

**Remark 18.** Let $X \in \mathcal{C}(\mathcal{A})$ and $N \subseteq \mathcal{A}(X)$. If we consider the ‘list’ $\mathcal{A}$ of all pairs
$(x_i, a_i)$ with $x_i \equiv a_i$, then the elements of $N$ index a ‘sublist’ $\mathcal{A}_N$. Then, $(X, N)$ is a
local no broken circuit set if and only if $\mathcal{A}_N$ is a basis of $\mathcal{A}$ with no *local external activity*
in the sense of d’Adderio and Moci [5, Section 5.3]

### 2.4 Cohomology

The cohomology (with complex coefficients) of the complements of toric arrangements
was studied by Looijenga [21] and De Concini and Procesi [8].

**Theorem 40** ([8, Theorem 4.2]). Consider a toric arrangement $\mathcal{A}$. The Poincaré polynomial of $M(\mathcal{A})$
*can be expressed as follows*:

$$P_{\mathcal{A}}(t) = \sum_{j=0}^{\infty} \dim H^j(M(\mathcal{A}); \mathbb{C}) t^j = \sum_{j=0}^{\infty} |\mathcal{N}_j| (t + 1)^{k-j} t^j.$$  

This result was reached in [8] by computing de Rham cohomology, in [21] via spectral sequence computations. In the special case of (totally) unimodular arrangements, De Concini and Procesi also determine the algebra structure of $H^*(M(\mathcal{A}), \mathbb{C})$ by formality of $M(\mathcal{A})$ [8, Section 5].

### 2.5 The homotopy type of complexified toric arrangements

From now on in this paper we will think of $\mathcal{A}$ as being a complexified (primitive, essential) toric arrangement.

The complement of a complexified toric arrangement $\mathcal{A}$ has the homotopy type of a
finite cell complex, defined from the stratification of the real torus $T_{\Lambda}$ into chambers and
faces induced by the associated ‘real’ arrangement $\mathcal{A}^c$.

**Definition 41.** Consider a complexified toric arrangement $\mathcal{A} = \{(x_1, a_1), \ldots, (x_n, a_n)\}$, its chambers are the connected components of $M(\mathcal{A}^c)$. We denote the set of chambers of $\mathcal{A}$ by $\mathcal{T}(\mathcal{A})$.

The *faces* of $\mathcal{A}$ are the connected components of the intersections

$$\text{relint}(C \cap X) \text{ with } C \in \mathcal{T}(\mathcal{A}) X \in \mathcal{C}(\mathcal{A}).$$

The faces of $\mathcal{A}$ are the cells of a polyhedral complex, which we denote by $\mathcal{D}(\mathcal{A})$. http://doc.rero.ch
The topology of a (non regular) polyedral complex is encoded in an acyclic category, called the face category of the complex (see [6, §2.2.2] for some details on face categories, our Section 3 below for some basics about acyclic categories, [20] for a more comprehensive treatment).

**Definition 42.** The face category of a complexified toric arrangement is $\mathcal{F}(\mathcal{A}) = \mathcal{F}(\mathcal{D}(\mathcal{A}))$, i.e. the face category of the polyhedral complex $\mathcal{D}(\mathcal{A})$.

The lattice $\Lambda$ acts on $\mathbb{C}^n$ and on $\mathbb{R}^n$ as the group of automorphisms of the covering map $p$ of (2.4) above. Consider now the map $q : \mathcal{F}(\mathcal{A}) \rightarrow \mathcal{F}(\mathcal{A}^\dagger)$ induced by $p$.

**Proposition 43 ([6, Lemma 4.8]).** Let $\mathcal{A}$ be a complexified toric arrangement. The map $q : \mathcal{F}(\mathcal{A}^\dagger) \rightarrow \mathcal{F}(\mathcal{A})$ induces an isomorphism of acyclic categories

$$\mathcal{F}(\mathcal{A}) \cong \mathcal{F}(\mathcal{A}^\dagger)/\Lambda.$$  

**2.5.1 The Salvetti category**

Recall that the Salvetti complex for affine hyperplane arrangements makes use of the operation of Definition 18. We need a suitable analogon for toric arrangements.

**Proposition 44 ([6, Proposition 3.12]).** Let $\Lambda$ be a finite rank lattice, $\Gamma$ a sublattice of $\Lambda$. Let $\mathcal{A}$ a complexified toric arrangement on $T_\Lambda$ and recall the arrangement $\mathcal{A}_\Gamma$ from Definition 36. The projection $\pi_\Gamma : T_\Lambda \rightarrow T_\Gamma$ induces a morphism of acyclic categories

$$\pi_\Gamma : \mathcal{F}(\mathcal{A}) \rightarrow \mathcal{F}(\mathcal{A}_\Gamma).$$

Consider now a face $F \in \mathcal{F}(\mathcal{A})$. We associate to it the sublattice

$$\Gamma_F = \{\chi \in \Lambda \mid \chi \text{ is constant on } F\} \subseteq \Lambda$$

**Definition 45.** Consider a toric arrangement $\mathcal{A}$ on $T_\Lambda$ and a face $F \in \mathcal{F}(\mathcal{A})$. The restriction of $\mathcal{A}$ to $F$ is the arrangement $\mathcal{A}_F = \mathcal{A}_{\Gamma_F}$ on $T_{\Gamma_F}$.

We will write $\pi_F = \pi_{\Gamma_F} : \mathcal{F}(\mathcal{A}) \rightarrow \mathcal{F}(\mathcal{A}_F)$.

**Definition 46 ([6, Definition 4.1]).** Let $\mathcal{A}$ be a toric a arrangement on a complex torus $T_\Lambda$. The **Salvetti category** of $\mathcal{A}$ is the category $\text{Sal } \mathcal{A}$ defined as follows.

(a) The objects are the morphisms in $\mathcal{F}(\mathcal{A})$ between faces and chambers:

$$\text{Obj}(\text{Sal } \mathcal{A}) = \{m : F \rightarrow C \mid m \in \text{Mor}(\mathcal{F}(\mathcal{A})), C \in \mathcal{T}(\mathcal{A})\}.$$  

(b) The morphisms are the triples $(n, m_1, m_2) : m_1 \rightarrow m_2$, where $m_1 : F_1 \rightarrow C_1$, $m_2 : F_2 \rightarrow C_2 \in \text{Obj}(\text{Sal } \mathcal{A})$, $n : F_2 \rightarrow F_1 \in \text{Mor}(\mathcal{F}(\mathcal{A}))$ and $m_1, m_2$ satisfy the condition:

$$\pi_{F_1}(m_1) = \pi_{F_1}(m_2).$$
(c) Composition of morphisms is defined as:

\[(n', m_2, m_3) \circ (n, m_1, m_2) = (n \circ n', m_1, m_3),\]

whenever \(n\) and \(n'\) are composable.

**Remark 19.** The Salvetti category is an acyclic category in the sense of Definition 49.

**Definition 47.** Let \(\mathcal{A}\) be a complexified toric arrangement; its Salvetti complex is the nerve \(S(\mathcal{A}) = \Delta(\text{Sal}\mathcal{A})\).

**Theorem 48** ([6, Theorem 4.3]). The Salvetti complex \(S(\mathcal{A})\) embeds in the complement \(M(\mathcal{A})\) as a deformation retract.

**Remark 20.** As for the case of affine arrangements, the Salvetti category is the face category of a polyhedral complex, of which the toric Salvetti complex is a subdivision. If we need to distinguish between the two, we will call the first *cellular Salvetti complex* and the second *simplicial Salvetti complex*.

## 3 Discrete Morse theory

Our proof of minimality will consist in describing a sequence of cellular collapses on the toric Salvetti complex, which is not necessarily a regular cell complex. We need thus to extend discrete Morse theory from posets to acyclic categories.

The setup used in the textbook of Kozlov [20] happens to lend itself very nicely to such a generalization - in fact, once the right definitions are made, even the proofs given in [20] just need some minor additional observation.

**Definition 49.** An acyclic category is a small category where the only endomorphisms are the identities, and these are the only invertible morphisms.

An *indecomposable morphism* in an acyclic category is a morphism that cannot be written as the composition of two nontrivial morphisms. The *length* of a morphism \(m\) in an acyclic category is the maximum number of members in a decomposition of \(m\) in nontrivial morphisms. The *height* of an acyclic category is the maximum of the lengths of its morphisms: here we will restrict ourselves to acyclic categories of finite height.

A *rank function* on an acyclic category \(\mathcal{C}\) is a function \(\text{rk} : \text{Ob}(\mathcal{C}) \to \mathbb{N}\) such that \(\text{rk}^{-1}(0) \neq \emptyset\) and such that for every indecomposable morphism \(x \to y\), \(\text{rk}(x) = \text{rk}(y) - 1\). An acyclic category is called *ranked* if it admits a rank function.

A *linear extension* \(\prec\) of an acyclic category is a total order on its set of objects, such that

\[\text{Mor}(x, y) \neq \emptyset \implies x \prec y.\]

**Remark 21** (Acyclic categories and posets). Every partially ordered set can be viewed as an acyclic category whose objects are the elements of the poset and where \(|\text{Mor}(x, y)| = 1\) if \(x \leq y\), \(|\text{Mor}(x, y)| = 0\) else (see [20, Exercise 4.9]).

Conversely, to every acyclic category \(\mathcal{C}\) is naturally associated a partial order on the set \(\text{Ob}(\mathcal{C})\) defined by \(x \leq y\) if and only if \(\text{Mor}(x, y) \neq \emptyset\). We denote by \(\underline{\mathcal{C}}\) this poset and...
by $\cdot : \mathcal{C} \to \mathcal{C}$ the natural functor, with $\mathcal{C}$ viewed as a category as above. We say $\mathcal{C}$ is a poset if this functor is an isomorphism.

In the following sections we will freely switch between the categorical and set-theoretical point of view about posets.

**Remark 22 (Face categories).** The acyclic categories we will be concerned with will arise mostly as face categories of polyhedral complexes. Intuitively, we call polyhedral complex a $\text{CW}$ complex $X$ whose cells are polyhedra, and such that the attaching maps of a cell $x$ restrict to homeomorphisms on every boundary face of $x$. The face category then has an object for every cell of $X$ and an arrow $x \to y$ for every boundary cell of $y$ that is attached to $x$. See [6, Definition 2.6 and 2.8] for the precise definition.

Notice that the face category of a polyhedral complex is naturally ranked by the dimension of the cells.

**Remark 23 (Terminology).** We take the term *acyclic category* from [20]. The same name, in other contexts, is given to categories with acyclic nerve. The reader be warned: acyclic categories as defined here must by no means have acyclic nerve.

On the other hand, the reader should be aware that what we call “acyclic category” appears in the literature also as *loopless category* or as scwol (for “small category without loops”).

The data about the cellular collapses that we will perform are stored in so-called *acyclic matchings*.

**Definition 50.** A *matching* of an acyclic category $\mathcal{C}$ is a set $\mathcal{M}$ of indecomposable morphisms such that, for every $m, m' \in \mathcal{M}$, the sources and the targets of $m$ and $m'$ are four distinct objects of $\mathcal{C}$. A *cycle* of a matching $\mathcal{M}$ is an ordered sequence of morphisms

$$a_1b_1a_2b_2 \cdots a_nb_n$$

where

1. For all $i$, $a_i \not\in \mathcal{M}$ and $b_i \in \mathcal{M}$,
2. For all $i$, the targets of $a_i$ and $b_i$ coincide and the sources of $a_{i+1}$ and $b_i$ coincide - as do the sources of $a_1$ and $b_n$.

A matching $\mathcal{M}$ is called *acyclic* if it has no cycles. A *critical element* of $\mathcal{M}$ is any object of $\mathcal{C}$ that is neither source nor target of any $m \in \mathcal{M}$.

**Lemma 51.** A matching $\mathcal{M}$ of an acyclic category $\mathcal{C}$ is acyclic if and only if

1. for all $x, y \in \text{Ob} \mathcal{C}$, $m \in \mathcal{M} \cap \text{Mor}(x, y)$ implies $\text{Mor}(x, y) = \{ m \}$;
2. there is a linear extension of $\mathcal{C}$ where source and target of every $m \in \mathcal{M}$ are consecutive.
Proof. Recall from Remark 21 the poset $C$, and notice that for every matching $M$ of $C$, the set $M$ is a matching of $C$. Moreover, by Theorem 11.1 of [20], condition (b) above is equivalent to $M$ being acyclic.

To prove the statement, let first $M$ be a matching of $C$ satisfying (a) and (b). Because of (a), every cycle of $M$ maps to a cycle of $M$. Since $M$ is acyclic because of (b), $M$ must be acyclic too.

Let now $M$ be an acyclic matching of $C$, then $M$ must be acyclic, thus (b) holds. If (a) fails, say because of some $x, y \in \text{Ob} C$ with $\text{Mor}(x, y) \supseteq \{m, m'\}$ and $m \in M$, then $m' \not\in M$ (because $M$ is a matching) and the sequence $m'm$ is a cycle of $M$, contradicting the assumption.

A handy tool for dealing with acyclic matchings is the following result, which generalizes [20, Theorem 11.10].

**Lemma 52** (Patchwork Lemma). Consider a functor of acyclic categories $\varphi : C \to C'$ and suppose that for each object $c$ of $C'$ an acyclic matching $M_c$ of $\varphi^{-1}(c)$ is given. Then the matching $M := \bigcup_{c \in \text{Ob} C'} M_c$ of $C$ is acyclic.

**Proof.** We apply Lemma 51. Since $\text{Mor}_{\varphi^{-1}(c)}(x, y) = \text{Mor}_C(x, y)$ for all $c \in \text{Ob} C'$ and all $x, y \in \text{Ob}(\varphi^{-1}(c))$, condition (a) holds for $M$ because it holds for $M_c$.

Property (b) for $M$ is proved via the linear extension of $C$ obtained by concatenation of the linear extensions given by the $M_c$ on the categories $\varphi(c)$. □

The topological gist of Discrete Morse Theory is the so-called “Fundamental Theorem” (see e.g. [20, §11.2.2]). Here we state the part of it that will be needed below.

**Theorem 53.** Let $F$ be the face category of a finite polyhedral complex $X$, and let $M$ be an acyclic matching of $F$. Then $X$ is homotopy equivalent to a CW-complex $X'$ with, for all $k$, one cell of dimension $k$ for every critical element of $M$ of rank $k$.

**Proof.** A proof can be obtained applying [20, Theorem 11.15] to the filtration of $X$ with $i$-th term $F_i(X) = \bigcup_{j \leq i} x_j$, where $x_0, x_1, \ldots$ is an enumeration of the cells of $X$ corresponding to a linear extension of $F(X)$ in which source and target of every $m \in M$ are consecutive (such a linear extension exists by Lemma 51.(b)). □

**Remark 24.** Let $M$ be an acyclic matching of a polyhedral complex $X$.

(i) The boundary maps of the complex $X'$ in Theorem 53 can be explicitly computed by tracking the individual collapses, as in [20, Theorem 11.13.(c)].

(ii) We will call $M$ perfect if the number of its critical elements of rank $k$ is $\beta_k(X)$, the $k$-th Betti number of $X$. Note that if the face category of a complex $X$ admits a perfect acyclic matching, then $X$ is minimal in the sense of [14].
4 Stratification of the toric Salvetti complex

We now work our way towards the proof of minimality of complements of toric arrangements. We start here by defining a stratification of the toric Salvetti complex, in which each stratum corresponds to a local non broken circuit. Then, in the next section, we will exploit the structure of this stratification to define a perfect acyclic matching on the Salvetti Category.

4.1 Local geometry of complexified toric arrangements

We start by introducing the key combinatorial tool in order to have a ‘global’ control of the local contributions.

Consider a rank \( d \) complexified toric arrangement \( \mathcal{A} = \{(\chi_1, a_1), \ldots, (\chi_n, a_n)\} \). As usual write \( \chi_i(x) = x^{\alpha_i} \) for \( \alpha_i \in \mathbb{Z}^d \) and \( K_i = \{x \in T_\Lambda \mid \chi_i(x) = a_i\} \).

Define \( \mathcal{A}_0 := \{H_i = \ker \langle \alpha_i, \cdot \rangle \mid i = 1, \ldots, n\} \), a central hyperplane arrangement in \( \mathbb{R}^d \).

From now on, fix a chamber \( B \in T(\mathcal{A}_0) \) and a linear extension \( \prec_0 \) of \( T(\mathcal{A}_0)_B \).

Next, we introduce some central arrangements associated with the ‘local’ data.

**Definition 54.** For every face \( F \in T(\mathcal{A}) \) define the arrangement
\[
\mathcal{A}[F] = \{H_i \in \mathcal{A}_0 \mid \chi_i(F) = a_i\}.
\]
If \( Y \in C(\mathcal{A}) \) define
\[
\mathcal{A}[Y] = \{H_i \in \mathcal{A}_0 \mid Y \subseteq K_i\}.
\]

**Remark 25.** The linear extension \( \prec_0 \) of \( T(\mathcal{A}_0)_B \) induces as in Proposition 11 linear extensions \( \prec_F \) of \( T(\mathcal{A}[F])_{B_F} \) and \( \prec_Y \) of \( T(\mathcal{A}[Y])_{B_Y} \), for every \( F \in F(\mathcal{A}) \) and every \( Y \in C(\mathcal{A}) \).

Moreover, for \( F \in F(\mathcal{A}) \) and \( C, C' \in T(\mathcal{A}[F]) \) we denote by \( S_F(C, C') \) the set of separating hyperplanes of the arrangement \( \mathcal{A}[F] \), as introduced in Definition 8.

**Definition 55.** Given \( Y \in C(\mathcal{A}) \) let \( \widetilde{Y} \in L(\mathcal{A}_0) \) be defined as
\[
\widetilde{Y} := \bigcap_{Y \subseteq K_i} H_i.
\]
Moreover, for \( C \in T(\mathcal{A}[Y]) \) let \( X(Y, C) \supseteq Y \) be the layer determined by the intersection defined by Lemma 22 from \( \prec_Y \). Analogously, for \( C \in T(\mathcal{A}[F]) \) let \( X(F, C) \) be defined with respect to \( \prec_F \).

We write \( \widetilde{X}(Y, C) \) and \( \widetilde{X}(F, C) \) for the corresponding elements of \( L(\mathcal{A}[Y]) \) and \( L(\mathcal{A}[F]) \).

**Definition 56.** Let
\[
\mathcal{Y} := \{(Y, C) \mid Y \in C(\mathcal{A}), C \in T(\mathcal{A}[Y]), X(Y, C) = Y\}.
\]
For \( i = 0, \ldots, d \) let \( \mathcal{Y}_i := \{(Y, C) \in \mathcal{Y} \mid \dim(Y) = i\} \).
Example 57. Consider the toric arrangement \( \mathcal{A} = \{ (x, 1), (xy^{-1}, 1), (xy, 1) \} \) of Figure 2(a). In this and in the following pictures we consider the compact torus \((S^1)^2\) as a quotient of the square. Therefore we draw toric arrangements in a square (pictured with a dashed line), where the opposite sides are identified.

The layer poset consists of the following elements

\[ C(\mathcal{A}) = \{ P, Q, K_1, K_2, K_3, (\mathbb{C}^*)^2 \} . \]

Figures 2(b) and 2(c) show respectively the arrangements \( \mathcal{A}[P] \) and \( \mathcal{A}[Q] = \mathcal{A}_0 \).

Let \( \mathcal{Y} \) as in Definition 56. There is one element \( (P, D_0) \in \mathcal{Y} \) and two elements \( (Q, D_1), (Q, D_2) \in \mathcal{Y} \). Furthermore we have an element for each 1-dimensional layer \( (K_i, D_i) \in \mathcal{Y} \).

Lemma 58. Let \( \mathcal{A} \) be a rank \( d \) toric arrangement. For all \( i = 0, \ldots, d \), we have \( |\mathcal{Y}_i| = |\mathcal{N}_i| \).

Proof. This follows because for every \( i = 0, \ldots, d \),

\[ |\mathcal{N}_i| = \sum_{\substack{Y \in C(\mathcal{A}) \\dim Y = i}} |\text{nbc}_i(\mathcal{A}[Y])| \]

Every summand on the right hand side counts the number of generators in top degree cohomology or - equivalently - the number of top dimensional cells of a minimal CW-model of the complement of the complexification of \( \mathcal{A}[Y] \). By [12, Lemma 4.18 and Proposition 2] these top dimensional cells correspond bijectively to chambers \( C \in \mathcal{T}(\mathcal{A}[Y]) \) with \( X(Y, C) = Y \). Therefore

\[ |\mathcal{N}_i| = \sum_{\substack{Y \in C(\mathcal{A}) \\dim Y = i}} |\{ C \in \mathcal{T}(\mathcal{A}[Y]) \mid X(Y, C) = Y \}| = |\mathcal{Y}_i| . \]
Definition 59. Recall Definition 9 and define a function

\[ \xi_0 : \mathcal{Y} \to \mathcal{T}(\mathcal{A}_0)_B \]

\[ (Y, C) \mapsto \mu[\mathcal{A}[Y], \mathcal{A}_0](C) \]

Choose, and fix, a total order \( \preceq \) on \( \mathcal{Y} \) that makes this function order preserving (i.e., for \( y_1, y_2 \in \mathcal{Y} \), by definition \( \xi_0(y_1) \prec_0 \xi_0(y_2) \) implies \( y_1 \prec y_2 \)).

We now examine the local properties of the ordering \( \preceq \).

Definition 60. For \( F \in \mathcal{F}(\mathcal{A}) \) let \( \mathcal{Y}_F := \{(Y, C) \in \mathcal{Y} \mid F \subseteq Y \} \).

Since \( F \subseteq Y \) implies \( \mathcal{A}[Y] \subseteq \mathcal{A}[F] \), we can define a function

\[ \xi_F : \mathcal{Y}_F \to \mathcal{T}(\mathcal{A}[F]) \]

\[ (Y, C) \mapsto \mu[\mathcal{A}[Y], \mathcal{A}[F]](C) \]

Remark 26. By Lemma 10, \( \mu[\mathcal{A}[F], \mathcal{A}_0] \circ \xi_F = \xi_0 \) on \( \mathcal{Y}_F \). Therefore, for \( y_1, y_2 \in \mathcal{Y}_F \), \( \xi_F(y_1) \prec_F \xi_F(y_2) \) implies \( \xi_0(y_1) \prec_0 \xi_0(y_2) \), and thus \( y_1 \prec y_2 \).

Proposition 61. For all \( F \in \mathcal{F}(\mathcal{A}) \) and every \( y = (Y, C) \in \mathcal{Y}_F \),

\[ X(F, \xi_F(y)) = Y. \]

Proof. We will use the lattice isomorphisms \( \mathcal{L}(\mathcal{A}[F]) \cong \mathcal{L}(\mathcal{A}[Y]) \cong \mathcal{C}(\mathcal{A}) \). By definition we have that

\[ \xi_F(y) = \mu[\mathcal{A}[Y], \mathcal{A}[F]](C) = \min\{K \in \mathcal{T}(\mathcal{A}[F]) \mid K \subseteq C\} \]

and therefore \( \mathcal{A}[F]_{\xi_F(y)} \cap S_F(\mathcal{A}[F]_{\xi_F(y)}, C_1) \neq \emptyset \) for all \( C_1 \prec_F \mathcal{A}[F]_{\xi_F(y)} \), which shows that \( \tilde{Y} \geq \tilde{X}(\mathcal{A}[F]_{\xi_F(y)}) \) in \( \mathcal{L}(\mathcal{A}[F]) \) and thus \( Y \geq X(F, \xi_F(y)) \) in \( \mathcal{C}(\mathcal{A}) \). Now, for every layer \( Z \) with \( Z \preceq Y \) we have that \( \mathcal{A}[Z] \subseteq \mathcal{A}[Y] \). Because by definition \( Y = X(Y, C) \), we have \( \tilde{Z} \preceq \tilde{Y} = \tilde{X}(Y, C) \) in \( \mathcal{L}(\mathcal{A}[Y]) \) and so there is \( C_2 \prec_Y C \) with \( S_Y(C_2, C) \cap \mathcal{A}[Y]_{\tilde{Z}} = \emptyset \).

Let \( C_3 := \mu[\mathcal{A}[Y], \mathcal{A}[F]](C_2) \). We have \( C_3 \subseteq C_2 \) and \( \mathcal{A}[F]_{\xi_F(y)} \subseteq C \), therefore \( S_F(C_3, \mathcal{A}[F]_{\xi_F(y)}) \cap \text{supp}(\tilde{Z}) = \emptyset \), and \( C_3 \prec_F \mathcal{A}[F]_{\xi_F(y)} \) by \( C_2 \prec_Y C \). This means \( Z \not\geq X(F, \xi_F(y)) \), and the claim follows.

Lemma 62. For \( F \in \mathcal{F}(\mathcal{A}) \) and \( C \in \mathcal{T}(\mathcal{A}[F]) \) we have

\[ \xi_F(X_C, \sigma_{\mathcal{A}[X_C]}(C)) = C \]

In particular \( \xi_F : \mathcal{Y}_F \to \mathcal{T}(\mathcal{A}[F]) \) is a bijection.

Proof. Using the definition of \( \xi_F \) and Corollary 23 we have

\[ \xi_F(X_C, \sigma_{\mathcal{A}[X_C]}(C)) = \mu[\mathcal{A}[X_C], \mathcal{A}[F]](\sigma_{\mathcal{A}[X_C]}(C)) \]

\[ = \min\{K \in \mathcal{T}(\mathcal{A}[F]) \mid K_{X_C} = C_{X_C}\} = C. \]

Letting \( \beta_F : \mathcal{T}(\mathcal{A}[F]) \to \mathcal{Y}_F \) be defined by \( C \mapsto (X_C, \sigma_{\mathcal{A}[X_C]}(C)) \), the above means \( \xi_F \circ \beta_F = \text{id} \), therefore the map \( \xi_F \) is surjective. Injectivity of \( \xi_F \) amounts now to proving \( \beta_F \circ \xi_F = \text{id} \), which is an easy check of the definitions.

Corollary 63. For \( y_1, y_2 \in \mathcal{Y}_F \), \( y_1 \prec y_2 \) if and only if \( \xi_F(y_1) \preceq_F \xi_F(y_2) \).
4.2 Lifting faces and morphisms

We now relate our constructions to the covering $\mathcal{A}^\dagger$ of $\mathcal{A}$ of §2.2.2. Recall that $\Lambda$ acts freely on $\mathcal{F}(\mathcal{A}^\dagger)$ and that $q : \mathcal{F}(\mathcal{A}^\dagger) \to \mathcal{F}(\mathcal{A}) = \mathcal{F}(\mathcal{A}^\dagger)/\Lambda$ is the projection to the quotient (compare Proposition 43).

**Remark 27.** Fix a face $F \in \text{Ob} \mathcal{F}(\mathcal{A})$, and choose a lifting $F^\dagger$ in $\mathcal{F}(\mathcal{A}^\dagger)$. Then the arrangements $\mathcal{A}^\dagger_{F^\dagger}$ and $\mathcal{A}[F]$ differ only by a translation. Thus we have natural isomorphisms of posets $\mathcal{F}(\mathcal{A}[F]) \simeq \mathcal{F}(\mathcal{A}^\dagger_{F^\dagger}) \simeq \mathcal{F}(\mathcal{A}^\dagger)_{\geq F^\dagger}$.

In the following we will identify these posets and, in particular, define a functor of acyclic categories $q : \mathcal{F}(\mathcal{A}[F]) \to \mathcal{F}(\mathcal{A})$ according to the restriction of $q : \mathcal{F}(\mathcal{A}^\dagger) \to \mathcal{F}(\mathcal{A})$ to $\mathcal{F}(\mathcal{A}^\dagger)_{\geq F^\dagger}$.

Given a face $G$ of $\mathcal{F}(\mathcal{A}[F])$ we will write $q(G)$ for the image under the covering $q$ (see Proposition 43) of the corresponding face of $\mathcal{F}(\mathcal{A}^\dagger)_{\geq F^\dagger}$.

**Remark 28** (Notation). Recall that we identify posets (such as $\mathcal{F}(\mathcal{A})$ or $\mathcal{F}(\mathcal{A}[F])$) with the associated acyclic categories, as explained in Remark 21. In particular, if $x, y$ are elements in a poset with $x \leq y$, we will take the notation $x \leq y$ also to stand for the unique morphism $x \to y$ in the associated category.

Now, given a morphism $m : F \to G$ of $\mathcal{F}(\mathcal{A})$, for every choice of a $F^\dagger \in \mathcal{F}(\mathcal{A}^\dagger)$ lifting $F$, there is a unique morphism $F^\dagger \leq G^\dagger$ lifting $m$. We have $\mathcal{F}(\mathcal{A}[G]) \subseteq \mathcal{F}(\mathcal{A}^\dagger_{F^\dagger})$ (see Remark 4)

**Definition 64.** Consider a toric arrangement $\mathcal{A}$ on $T_\Lambda \cong (\mathbb{C}^*)^k$ and a morphism $m : F \to G$ of $\mathcal{F}(\mathcal{A})$. Because of the freeness of the action of $\Lambda$, for every choice of a $F^\dagger \in \mathcal{F}(\mathcal{A}^\dagger)$ lifting $F$, there is a unique morphism $F^\dagger \leq G^\dagger$ lifting $m$.

To $m$ we associate

(a) the order preserving function $i_m : \mathcal{F}(\mathcal{A}[G]) \to \mathcal{F}(\mathcal{A}[F])$ corresponding to the inclusion $\mathcal{F}(\mathcal{A}^\dagger_{G^\dagger}) \subseteq \mathcal{F}(\mathcal{A}^\dagger_{F^\dagger})$ (see Remark 4) under the identification of Remark 27.

(b) the face $F_m \in \mathcal{F}(\mathcal{A}[F])$ defined by $F_m := i_m(\hat{G})$ where $\hat{G}$ denotes the unique minimal element of $\mathcal{F}(\mathcal{A}[G])$.

Clearly then $\hat{G} = F_{\text{id}_G}$. In the following we will abuse notation for the sake of transparency and, given a face $G$ of $\mathcal{F}(\mathcal{A})$, we will write $G_{\text{id}}$ for $F_{\text{id}_G}$.

**Example 65.** Consider the arrangement $\mathcal{A}$ of Figure 2. Figure 3 illustrates the maps $i_m$ and $i_n$ for the morphisms $m : P \to F$ and $n : Q \to F$. 
Figure 3: $F_m$ and the map $i_m$

**Remark 29.** Every choice of positive sides for the elements of $\mathcal{A}_0$ determines a corresponding choice for all the elements of $\mathcal{A}^1$. Then given $m : F \to G$ and any lift $G^1$ of $G$, in terms of sign vectors and identifying each $H \in \mathcal{A}[F]$ with its unique translate which contains $G^1$:

$$\gamma_{F_m}[\mathcal{A}[F]] = \gamma_{G^1}[\mathcal{A}^1]|_{\mathcal{A}[F]}.$$ 

In particular, when $G$ is a chamber, then $F_m$ also is.

**Lemma 66.** Recall the setup of Definition 64.

(a) If $F \xrightarrow{m} G \xrightarrow{n} K$ are morphisms of $\mathcal{F}(\mathcal{A})$, then

$$i_{nom} = i_m \circ i_n \quad \text{thus} \quad i_m(F_n) = F_{nom}.$$ 

(b) Let $m : F \to G$ be a morphism of $\mathcal{F}(\mathcal{A})$. Then, for every morphism $n$ of $\mathcal{A}[G]$, we have $q(i_m(n)) = q(n)$ and, in particular, for every face $K$ of $\mathcal{A}[G]$, $q(i_m(K)) = q(K)$.

(c) Let $m : G \leq K$ be a morphism of $\mathcal{F}(\mathcal{A}[F])$. Then there are morphisms $n : F \to q(G)$ and $m^1$ of $\mathcal{F}(\mathcal{A})$ with

$$i_n(q(G)_{id} \leq F_{m^1}) = m$$

**Proof.** Parts (a) and (b) are immediate rephrasing of the definitions. For part (c) let $n := q(F_{id} \leq G)$ and $m^1 := q(m)$.  

4.3 **Definition of the strata**

Each stratum will be associated to an element of $\mathcal{Y}$, and we will think of the Salvetti category as being ‘built up’ from strata according to the ordering of $\mathcal{Y}$. 
Definition 67. Define the map \( \theta : \text{Sal}(\mathcal{A}) \to \mathcal{Y} \) as follows
\[
\theta : (m : F \to C) \mapsto (X(F,F_m), \sigma_{\mathcal{A}[X(F,F_m)]}(F_m))
\]

Remark 30. For every object \( m : F \to C \) of \( \text{Sal}(\mathcal{A}) \) we have \( \xi_F(\theta(m)) = F_m \).

Lemma 68. For \( m : G \to C, m' : G \to C' \in \zeta \), if \( \theta(m) \not\succeq \theta(m') \) then \( F_m \prec_G F_{m'} \).

Proof. If \( \theta(m) \not\succeq \theta(m') \), then with Remark 30 and Corollary 63, \( F_m = \xi_G(\theta(m)) \prec_G \xi_G(\theta(m')) = F_{m'} \).

Definition 69. Given a complexified toric arrangement \( \mathcal{A} \) on \( (\mathbb{C}^*)^d \), we consider the following stratification of \( \text{Sal}(\mathcal{A}) \) indexed by \( \mathcal{Y} \): \( \text{Sal}(\mathcal{A}) = \bigcup_{(Y,C) \in \mathcal{Y}} S_{(Y,C)} \) where
\[
S_{(Y,C)} = \{ m \in \text{Sal}(\mathcal{A}) | \exists (m \to n) \in \text{Mor}(\text{Sal}(\mathcal{A})), n \in \theta^{-1}(Y,C) \}.
\]

Moreover, recall from Definition 59 the total ordering \( \triangleright \) on \( \mathcal{Y} \) and define
\[
N_y = S_y \setminus \bigcup_{y' \triangleright y} S_{y'}.
\]
Example 70. Consider the toric arrangement $\mathcal{A}$ of Figure 2. Figure 4 (a) shows two strata of the stratification on $\text{Sal} \mathcal{A}$ of Definition 69.

The stratum $S_{((C^\ast)^2,D)}$ appears with a dotted shading, while the stratum $N_{(K_2,D_2)}$ has a solid shading. Thus $N_{(K_2,D_2)}$ consists of two 1-dimensional layers and two 2-dimensional layers. Figure 4 (b) depicts the rank 1 arrangement $\mathcal{A}^{K_2}$. The category $N_{(K_2,D_2)}$ is showed in Figure 4 (c) and it is isomorphic to $\mathcal{F}(\mathcal{A}^{K_2})^{op}$ (in this case $\mathcal{F}(\mathcal{A}^{K_2})^{op} \cong \mathcal{F}(\mathcal{A}^{K_2})$).

5 The topology of the Strata

We now want to show that, for $y \in \mathcal{Y}$, the category $N_y$ is isomorphic to the face category of a complexified toric arrangement. The main result of this section is the following.

Theorem 71. Consider a complexified toric arrangement $\mathcal{A}$ and for $y = (Y,C) \in \mathcal{Y}$ let $N_y$ be as in Definition 69. Then there is an isomorphism of acyclic categories

$$N_{(Y,C)} \cong \mathcal{F}(\mathcal{A}^Y)^{op}$$

The main idea for proving this theorem is to use the ‘local’ combinatorics of the (hyperplane) arrangements $\mathcal{A}[F]$ to understand the ‘global’ structure of the strata in $\text{Sal}(\mathcal{A})$. We carry out this ‘local-to-global’ approach by using the language of diagrams.

5.1 The category $AC$

Let $Cat$ denote the category of small categories. We define $AC$ to be the full subcategory of $Cat$ consisting of acyclic categories (see Definition 49, compare [20]).

Colimits in $AC$ do not coincide with colimits taken in $Cat$. In the following, we will need an explicit description of colimits in $AC$, at least for the special class of diagrams with which we will be concerned.

Definition 72. Let $I$ be an acyclic category. A diagram $\mathcal{D} : I \to AC$ of acyclic categories is called geometric if

(i) - for every $X \in \text{Ob}(I)$, $\mathcal{D}(X)$ is ranked and
- for every $f \in \text{Mor}(I)$, $\mathcal{D}(f)$ is rank-preserving;

(ii) for every $X \in \text{Ob}(I)$ and every $x \in \text{Mor}(\mathcal{D}(X))$ there exist
- $\tilde{X} \in \text{Ob}(I)$,
- $f \in \text{Mor}_I(\tilde{X},X)$ and
- $\tilde{x} \in \text{Mor} \mathcal{D}(\tilde{X})$ with $\mathcal{D}(f)(\tilde{x}) = x$

such that: for every morphism $g \in \text{Mor}_I(Y,X)$ and every $y \in \mathcal{D}(g)^{-1}(x)$ there exists a morphism $\tilde{g} \in \text{Mor}_I(\tilde{X},Y)$ such that $\mathcal{D}(\tilde{g})(\tilde{x}) = y$.

Remark 31. From the definition it follows that the morphism $\tilde{x}$ in (ii) is unique.
**Definition 73.** Define a relation $\sim$ on $\bigsqcup_{X \in \text{Ob}\mathcal{I}} \text{Mor}(\mathcal{D}(X))$ as follows: for $x \in \text{Mor}(\mathcal{D}(X))$ and $y \in \text{Mor}(\mathcal{D}(Y))$ let $x \sim y$ if in there is

- an object $Z \in \text{Ob}(\mathcal{I})$, a morphism $z \in \text{Mor}(\mathcal{D}(Z))$
- morphisms $f_X : Z \to X$, $f_Y : Z \to Y$ of $\mathcal{I}$

such that $\mathcal{D}(f_X)(z) = x$ and $\mathcal{D}(f_Y)(z) = y$.

Moreover, define a relation $\approx$ on $\bigsqcup_{X \in \text{Ob}\mathcal{I}} \text{Ob}(\mathcal{D}(X))$ by setting $a \approx b$ if $\text{id}_a \sim \text{id}_b$.

**Remark 32.** If $\mathcal{D}$ is a geometric diagram of acyclic categories, the observation that $x \sim y$ if and only if $\hat{x} = \hat{y}$, together with Remark 31, shows that $\sim$ and $\approx$ are in fact equivalence relations.

**Proposition 74.** Let $\mathcal{D} : \mathcal{I} \to \mathcal{AC}$ be a geometric diagram of acyclic categories. Then, the colimit of $\mathcal{D}$ exists and is given by the co-cone $(\mathcal{C}, (\gamma_X)_{X \in \text{Ob}\mathcal{I}})$ with

$$\text{Ob}(\mathcal{C}) = \bigsqcup_{X \in \text{Ob}\mathcal{I}} \text{Ob}(\mathcal{D}(X))/\sim, \quad \text{Mor}(\mathcal{C}) = \bigsqcup_{X \in \text{Ob}\mathcal{I}} \text{Mor}(\mathcal{D}(X))/\sim$$

(where $[m]_{\sim} : [x]_{\approx} \to [y]_{\approx}$ whenever $m : x \to y$, and for every $X \in \text{Ob}\mathcal{I}$, $x \in \text{Ob} \mathcal{D}(X)$, $m \in \text{Mor} \mathcal{D}(X)$:

$$\gamma_X(x) = [x]_{\approx}, \quad \gamma_X(m) = [m]_{\sim}.$$

**Proof.** One easily checks that $\mathcal{C}$ is a well-defined small category. We have to prove two claims.

**Claim 1:** $\mathcal{C}$ is acyclic.

**Proof:** Because the definition of a geometric diagram requires $\mathcal{D}(f)$ to be rank-preserving for all $f \in \text{Mor}\mathcal{I}$, we can define for all $[x]_{\approx} \in \text{Ob}\mathcal{C}$ a value $\nu([x]_{\approx}) := \text{rk} (x)$, where $x$ is any representant and the rank is taken in the appropriate category. Now, for every $X \in \text{Ob}\mathcal{I}$, every nonidentity morphism $m \in \text{Mor} \mathcal{D}(X)(x, y)$ has $\text{rk}(x) < \text{rk}(y)$ and thus $\nu([x]_{\approx}) < \nu([y]_{\approx})$ - in particular, $[m]_{\sim}$ is not an identity. This implies directly that the only endomorphisms of $\mathcal{C}$ are the identities. Moreover, if the morphism $[m]_{\sim}$ above is an invertible non-identity, then its inverse would be a morphism $[y]_{\approx} \to [x]_{\approx}$ - but since $\nu([x]_{\approx}) < \nu([y]_{\approx})$, no such morphism exists.

**Claim 2:** The co-cone $(\mathcal{C}, (\gamma_X)_{X \in \text{Ob}\mathcal{I}})$ satisfies the universal property.

**Proof:** Let $(\mathcal{C}', (\gamma'_X)_{X \in \text{Ob}\mathcal{I}})$ be a co-cone over $\mathcal{D}$. We have to show that there is a unique morphism of co-cones $\Psi : (\mathcal{C}, (\gamma_X)_{X \in \text{Ob}\mathcal{I}}) \to (\mathcal{C}', (\gamma'_X)_{X \in \text{Ob}\mathcal{I}})$.

In order to do that, notice that if $y \in [x]_{\sim} \in \text{Mor}\mathcal{C}$, there are $X, Y, Z \in \text{Ob}\mathcal{I}, f_X, f_Z \in \text{Mor} \mathcal{I}$ and $z \in \text{Mor} \mathcal{D}(Z)$ as in Definition 73, such that

$$\gamma'_X(x) = \gamma'_Z f_X(z) = \gamma'_Y f_Y(z) = \gamma'_Y(y).$$

This proves that the assignments

$$\Psi[x]_{\approx} := \gamma'_X(x), \quad \Psi[m]_{\sim} := \gamma'_X(m),$$
where $X$ is such that $x$ is in $\mathcal{D}(X)$, do not depend on the choice of the representant $x$ and thus define a function $\Psi : \mathcal{C} \to \mathcal{C}'$. A routine check shows functoriality and uniqueness of $\Psi$.

\section{5.2 Proof of Theorem 71}

Throughout this section let $\mathcal{A}$ be a complexified toric arrangement and recall the notational conventions of Section 4.2, in particular Remark 27 and Remark 28.

\textbf{Definition 75} (A diagram for the face category of the compact torus).

$$\mathcal{F}(\mathcal{A}) := F : \mathcal{F}(\mathcal{A})^\text{op} \to \mathcal{AC}$$

$$F \mapsto \mathcal{F}(\mathcal{A}[F])$$

$$(m : F \to G) \mapsto (i_m : \mathcal{F}(\mathcal{A}[G]) \to \mathcal{F}(\mathcal{A}[F]))$$

After these preparations, we turn to the diagrams.

\textbf{Lemma 76.} For the diagram $\mathcal{F}$ of Definition 75 we have

$$\text{colim} \mathcal{F}(\mathcal{A}) = \mathcal{F}(\mathcal{A}).$$

\textbf{Proof.} We begin by noticing that $\mathcal{F}$ is a geometric diagram. Indeed, for a morphism $m : G \leq K$ of $\mathcal{F}(\mathcal{F})$ let $n$ and $m^1$, be obtained as in Lemma 66.(c). Then

$$\hat{F} := q(G), \quad f := n^\text{op}, \quad \hat{m} := (q(G)_{\text{id}} \leq F_{m^1}).$$

satisfy the requirements of Definition 72.

Accordingly, the objects and morphisms of $\text{colim} \mathcal{F}$ are given as in Proposition 74, with the relation $\sim$ generated by $n \sim \mathcal{F}(m)(n)$ for every morphism $m : F \to G$ of $\mathcal{F}(\mathcal{A})$ and every morphism $n : G' \to G''$ of $\mathcal{F}(\mathcal{A}[G])$ and, accordingly, the relation $\approx$ generated by $G' \approx \mathcal{F}(m)(G')$ for all morphisms $(m : F \to G) \in \text{Mor}(\mathcal{F}(\mathcal{A}))$ and all $G'' \in \text{Obj}(\mathcal{F}(\mathcal{A}[G]))$. For the sake of notational transparency we will omit explicit reference to $\sim$ and $\approx$ and denote equivalence classes with respect to these equivalence relations simply by $[\cdot]$, to avoid confusion with the square brackets used to identify elements of the Salvetti complex.

We prove the Lemma by constructing an isomorphism $\Phi : \mathcal{F}(\mathcal{A}) \to \text{colim} \mathcal{F}$ as follows. For every object $F \in \mathcal{F}(\mathcal{A})$ define $\Phi(F) := [F_{\text{id}}]$, (recall from Definition 64 that $F_{\text{id}}$ is a face in $\mathcal{F}(\mathcal{A}[F])$), for every morphism $m : F \to G$ in $\mathcal{F}(\mathcal{A})$ define

$$\Phi(m) =: [F_{\text{id}} \leq F_m].$$

The bijectivity of $\Phi$ is easily seen, so we only need to show the functoriality of $\Phi$. To this end consider two composable morphisms $F \xrightarrow{m} G \xrightarrow{n} H$. Using Lemma 66.(a) we get

$$\Phi(n) \circ \Phi(m) = [G_{\text{id}} \leq G_n] \circ [F_{\text{id}} \leq F_m]$$

$$= [\mathcal{F}(m)(G_{\text{id}} \leq G_n)] \circ [F_{\text{id}} \leq F_m] = [i_m(G_{\text{id}}) \leq i_m(G_n)] \circ [F_{\text{id}} \leq F_m]$$

$$= [F_{\text{id}} \leq F_{\text{nom}}] \circ [F \leq F_m] = [F \leq F_{\text{nom}}] = \Phi(n \circ m).$$

$\square$
Definition 77 (A diagram for the Salvetti category).

$$D(\mathcal{A}) := D : F(\mathcal{A})^{op} \to AC;$$

$$F \mapsto \text{Sal}(A[F]);$$

$$(m : F \to G) \mapsto j_m : \text{Sal}(\mathcal{A}[G]) \leftrightarrow \text{Sal}(\mathcal{A}[F])$$

where $j_m([G, C]) = [i_m(G), i_m(C)]$.

Lemma 78.

$$\text{colim } D(\mathcal{A}) = \text{Sal}(\mathcal{A})$$

Proof of Lemma 78. The proof follows the outline of the proof of Lemma 76, and starts by noticing that the diagram $D$, too, is geometric. Indeed, let $x : [K_1, C_1] \leq [K_2, C_2]$ be a morphism in $\text{Sal}(\mathcal{A}[F])$. Correspondingly, we have morphisms $m_0 : K_2 \leq K_1$, $m_1 : K_1 \leq C_1$, $m_2 : K_2 \leq C_2$ of $F(\mathcal{A}[F])$. For $i = 0, 1, 2$ let $n_i, m_i$ be obtained from $m_i$ as in Lemma 66.(c). Then a straightforward check of the definitions shows that the assignment

$$\hat{F} := q(K_2), \quad f := n^{op}, \quad \hat{x} : [(K_2)_{id}, F_{m_2}] \leq [F_{m_0}, F_{m_{op}m_0}]$$

is well-defined and satisfies the requirement of Definition 72.

Thus Proposition 74 again applies and, accordingly, we write objects and morphisms of $\text{colim } D$ as equivalence classes of the appropriate relations, that we will again denote by $[\cdot]$.

An isomorphism $\Psi : \text{Sal}(\mathcal{A}) \to \text{colim } D$ can now be defined as follows. For an object $m : F \to C$ of $\text{Sal}(\mathcal{A})$ define $\Psi(m) = [[[F_{id}, F_{m}]]]$ (notice that, considering $m$ as a morphism of $F(\mathcal{A})$, we have $\Psi(m) = \Phi(m)$). For a morphism $(n, m_1, m_2)$ of $\text{Sal}(\mathcal{A})$ with $m_i : F_i \to C_i$ and $n : F_2 \to F_1$ define

$$\Psi(n, m_1, m_2) = D(n)([[F_{id}, F_{m_1}]] \leq [(F_{2})_{id}, F_{m_2}]] =$$

$$[[i_n(F_{1})_{id}, i_n(F_{m_1})] \leq [(F_{2})_{id}, F_{m_2}]] = [[[F_{n}, F_{m_{0}m_{n}}] \leq [(F_{2})_{id}, F_{m_2}]]$$

where in the last equality we used Lemma 66.(a).

Remark 33. Using Remark 66.(c) we have that every element $\varepsilon \in \text{Ob}(\text{colim } D(\mathcal{A}))$ has a (unique) representant $[F_{id}, C] \in S(\mathcal{A}[F])$ such that for every other representant $[G, K]$ with $\varepsilon = [G', K]$ there is a unique face $G \in F(\mathcal{A})$ and a unique morphism $m : F \to G$ with $[G', K] = [F_{m}, i_m(C)]$.

Lemma 79. Let $m : F \to G$ be a morphism of $F(\mathcal{A})$ and consider an $(Y, C) \in \mathcal{Y}_F$. Then the inclusion $j_m : \text{Sal}(\mathcal{A}[G]) \to \text{Sal}(\mathcal{A}[F])$ restricts to an inclusion

$$j_m : S_{\mathcal{F}G(Y, C)} \to S_{\mathcal{F}G(Y, C)}.$$

Remark 34. Note that, given any chamber $C$ of $\mathcal{A}[G]$ and any chamber $C'$ of $\mathcal{A}[F]$, there is a natural inclusion $S(\mathcal{A}[G]_C \subset S(\mathcal{A}[F]_C' \subseteq S(\mathcal{A}[F])$ if and only if $S(i_m(C), C') \cap \mathcal{A}[G] = \emptyset$. 
Proof. With Remark 34 we only need to show that $S(i_m(\xi_G(Y, C)), \xi_F(Y, C)) \cap \mathcal{A}[G] = \emptyset$. Let $H \in \mathcal{A}[G]$, then

$$\gamma_{i_m(\xi_G(Y, C))}(H) = \gamma_{\xi_G(Y, C)}(H) = \gamma_{\xi_F(Y, C)}(H) \implies H \notin S(i_m(\xi_G(Y, C)), \xi_F(Y, C))$$

where the last equality follows from the fact that $\xi_F(Y, C) \subseteq \xi_G(Y, C)$. \hfill $\square$

Lemma 79 allows us to state the following definition.

**Definition 80.** Given $(Y, C) \in \mathcal{Y}$ let

$$\mathcal{E}(Y, C) : \mathcal{F}(\mathcal{A})^{op} \to \mathcal{AC}$$

$$F \mapsto S(\mathcal{A}[F]_{\xi_F(Y, C)}) \quad (m : F \to G) \mapsto (j_m)_{|_{\mathcal{E}(Y, C)(G)}}$$

**Lemma 81.** Let $(Y, C) \in \mathcal{Y}$, then

$$\colim \mathcal{E}(Y, C) = \mathcal{S}(Y, C)$$

**Proof.** We consider the isomorphism $\Psi : \text{Sal}(\mathcal{A}) \to \colim \mathcal{D}$ of Lemma 78. We want to show that $\Psi(\mathcal{S}(Y, C)) = \colim \mathcal{E}(Y, C)$, and we do this in two steps.

**Step 1:** $\colim \mathcal{E}(Y, C) \subseteq \Psi(\mathcal{S}(Y, C))$.

Let $[G, K] \in \colim \mathcal{E}(Y, C)$, then (recall Remark 33) there is a morphism of $\mathcal{F}(\mathcal{A})$ $m : F \to G$ such that $[F_m, i_m(K)] \in \mathcal{S}(\xi_F(Y, C)) \subseteq \text{Sal}(\mathcal{A}[F])$, i.e.

$$[F_m, i_m(K)] \leq [F_{id}, \xi_F(Y, C)]$$

Taking the preimage through $\Psi$ of this relation we get a morphism

$$\Psi^{-1}([G, K]) \to \Psi^{-1}([F_{id}, \xi_F(Y, C)]) \in \text{Mor}(\text{Sal}(\mathcal{A}))$$

Now, using Proposition 61 we have

$$\theta(\Psi^{-1}([F_{id}, \xi_F(Y, C)])) = (X(F, \xi_F(Y, C)), \sigma_{\mathcal{A}[Y]} \xi_F(Y, C))$$

$$= (Y, \sigma_{\mathcal{A}[Y]} \circ \mu[\mathcal{A}[Y], \mathcal{A}[F]](C)) = (Y, C).$$

Therefore $\Psi^{-1}([G, K]) \in \mathcal{S}(Y, C)$, so $[G, K] \in \Psi(\mathcal{S}(Y, C))$, as was to be proved.

**Step 2:** $\Psi(\mathcal{S}(Y, C)) \subseteq \colim \mathcal{E}(Y, C)$.

Consider now $(m : G \to K) \in \mathcal{S}(Y, C)$. Then there is a morphism $(h, m, n) : m \to n \in \text{Mor}(\text{Sal}(\mathcal{A}))$ with $n : F \to K'$, $h : F \to G$ and $\theta(n) = (Y, C)$. In particular, in view of Remark 30, we get $F_n = \xi_F(\theta(n)) = \xi_F(Y, C)$.

Applying $\Psi$ to the morphism $(h, m, n)$, in $\text{Sal}(\mathcal{A}[F])$ we obtain

$$j_n([G, G_m]) \leq [F, F_n] = [F, \xi_F(Y, C)], \text{ thus } j_n([G, G_m]) \in \mathcal{S}(\xi_F(Y, C)),$$

and we conclude that

$$\Psi(m) = [G, G_m] = [j_n([G, G_m])] \in \colim \mathcal{E}(Y, C),$$

as required.
**Definition 82.** Given \((Y, C) \in \mathcal{Y}\), define

\[
\mathcal{G}_{(Y, C)} : \mathcal{F}(\mathcal{A}^Y)^{op} \to AC
\]

\[
F \mapsto \mathcal{N}_{\xi_F(Y, C)}
\]

\[
(m : F \to G) \mapsto (j_m)_{\mathcal{G}_{(Y, C)}(G)}
\]

**Remark 35.** To prove that the diagram \(\mathcal{G}_{(Y, C)}\) is well defined, we have to show that for every morphism \(m : F \to G\) of \(\mathcal{F}(\mathcal{A}^Y)\)

\[
j_m(\mathcal{N}_{\xi_F(Y, C)}) \subseteq \mathcal{N}_{\xi_F(Y, C)}.
\]

This follows because by Proposition 61 we have \(X(F, \xi_F(Y, C)) = Y\), and thus with [12, Lemma 4.18] we can rewrite

\[
\mathcal{N}_{\xi_F(Y, C)} = \{[G, K] \in \text{Sal}(\mathcal{A}[F]) \mid G \in \mathcal{F}(\mathcal{A}[F]^Y), K_G = \xi_F(Y, C)_G\}.
\]

Now let \([G', C'] \in \mathcal{N}_{\xi_C(Y, C)}\). Then since \(G' \subseteq \tilde{Y}\) we have \(i_m(G') \subseteq \mathcal{F}(\mathcal{A}[F]^Y)\), and from \(\xi_F(Y, C) \subseteq \xi_G(Y, C)\) we conclude \(i_m(C') \subseteq \mathcal{F}(\mathcal{A}[F]^Y)\). Therefore \(j_m([G', C']) = [m(G'), m(C')] \in \mathcal{N}_{\xi_{\xi_F(Y, C)}},\) and the inclusion (5.2) is proved.

**Lemma 83.**

\[
\text{colim } \mathcal{G}_{(Y, C)} = \mathcal{N}_{(Y, C)}
\]

**Proof.** Again the proof is in two steps.

**Step 1:** \(\text{colim } \mathcal{G}_{(Y, C)} \subseteq \mathcal{N}_{(Y, C)}\).

For this, let \([F, K] \in \text{colim } \mathcal{G}_{(Y, C)}\) and suppose \([F, K] \notin \mathcal{N}_{(Y, C)}\). Then \([F, K] \in \text{colim } \mathcal{G}_{(Y', C')}\) for some \((Y', C') < (Y, C)\). Now, since \([F, K] \in \text{colim } \mathcal{G}_{(Y, C)}\) there exist a point \(P \in \mathcal{F}(\mathcal{A})\) and a morphism \(m : P \to F\) with \([P_m, i_m(K)] \in \mathcal{N}_{\xi_F(Y, C)}\). Therefore, in \(\mathcal{F}[P]\) we have \([P_m, i_m(K)] \subseteq [P, \xi_F(Y, C)]\), which implies \(K_{P_m} = \xi_F(Y, C)_{P_m}\), and thus \(K = \sigma_{\mathcal{A}[F]}(K_{P_m}) = \xi_F(Y, C)\).

Similarly, since \([F, K] \in \text{colim } \mathcal{G}_{(Y', C')}\) there is a point \(Q \in \mathcal{F}(\mathcal{A})\) and a morphism \(n : Q \to F\) with \([Q_n, i_n(K)] \in \mathcal{S}_{\xi_F(Y, C')}\). Then, as above, \(K = \xi_F(Y', C')\).

From the bijectivity proven in Lemma 62 we conclude \((Y', C') = (Y, C)\), which contradicts \((Y', C') < (Y, C)\), proving that \([F, K] \notin \mathcal{N}_{(Y, C)}\), as desired.

**Step 2:** \(\mathcal{N}_{(Y, C)} \subseteq \text{colim } \mathcal{G}_{(Y, C)}\).

Suppose \([F, K] \in \mathcal{N}_{(Y, C)} \setminus \text{colim } \mathcal{G}_{(Y, C)}\). Then \([F, K] \in \mathcal{S}_{\xi_F(Y', C')}\) for some point \(P \in \mathcal{F}(\mathcal{A})\) and some \((Y', C') < (Y, C)\). But then \([F, K] \in \text{colim } \mathcal{G}_{(Y', C')}\), thus \([F, K] \notin \mathcal{N}_{(Y, C)}\).
Proof. For each $F \in \mathcal{F}(\mathcal{A}^Y)$ define the isomorphisms $\mathcal{G}_{(Y,C)}(F) \to \mathcal{F}(\mathcal{A}^Y)^{op}(F)$ as follows

$$\mathcal{G}_{(Y,C)}(F) = \mathcal{N}_{F(Y,C)} \cong \mathcal{F}(\mathcal{A}^Y)^{op} = \mathcal{F}(\mathcal{A}^Y) = \mathcal{F}(\mathcal{A}^Y)^{op}(F).$$

Where the isomorphism in the middle comes from Theorem 25.

It can be easily checked that these isomorphisms are indeed morphisms of diagrams.

As a consequence of Lemma 84 we can write the following.

Proof of Theorem 71.

$$\mathcal{N}_{(Y,C)} = \text{colim} \mathcal{G}_{(Y,C)} \cong \text{colim} \mathcal{F}(\mathcal{A}^Y) = \mathcal{F}(\mathcal{A}^Y)^{op}.$$ 

\[ \square \]

6 Minimality of toric arrangements

In this section we will construct a perfect acyclic matching of the Salvetti category of a complexified toric arrangement. By Remark 24 this will imply minimality and, with it, torsion freeness of the arrangement’s complement.

6.1 Perfect matchings for the compact torus

Let $\mathcal{A}$ be a complexified toric arrangement in $T_\Lambda$ and recall the notations of Section 2.1. Choose a point $P \in \max C(\mathcal{A})$. Up to a biholomorphic transformation we may suppose that $P$ is the origin of the torus.

Let then $(\chi_1, a_1), \ldots, (\chi_d, a_d) \in \mathcal{A}$ be such that $\alpha_1, \ldots, \alpha_d$ are ($\mathbb{Q}$-) linearly independent and $P \in K_i$ for all $i = 1, \ldots, d$. For $i = 1, \ldots, d$ let $H_i^1$ denote the hyperplane of $\mathcal{A}^1$ lifting $K_i$ at the origin of $\text{hom}(\Lambda, \mathbb{R}) \simeq \mathbb{R}^d$. We identify for ease of notation $\Lambda \simeq \mathbb{Z}^d \subseteq \mathbb{R}^d$, and in particular think of $\alpha_i$ as the normal vector to $H_i^1$.

For $j \in [d]$ we consider the rank $j - 1$ lattice

$$\Lambda_j := \mathbb{Z}^d \cap \bigcap_{i \geq j} H_i^1.$$ 

Lemma 85. There is a basis $u_1, \ldots, u_d$ of $\Lambda$ such that for all $i = 1, \ldots, d$, the elements $u_1, \ldots, u_{i-1}$ are a basis of $\Lambda_i$.

Proof. The proof is by repeated application of the Invariant Factor Theorem, e.g. [4, Theorem 16.18], to the free $\mathbb{Z}$-submodule $\Lambda_j$ of $\Lambda_{j-1}$.

Let $(H_i^1)^+ := \{ x \in \mathbb{R}^d \mid \langle x, \alpha_i \rangle \geq 0 \}$.

Remark 36. In particular, $u_i \notin H_i^1$, hence $u_i(H_i^1) \neq H_i^1$. Moreover, without loss of generality we may suppose $u_i \in (H_i^1)^+$. 

http://doc.rero.ch
The lattice $\Lambda$ acts on $\mathbb{R}^d$ by translations. Given $u \in \Lambda$, let the corresponding translation be
\[ t_u : \mathbb{R}^d \to \mathbb{R}^d; \quad x \mapsto t_u(x) := x + u. \]

**Corollary 86.** For all $x \in \mathbb{R}^d$ and all $i < j \in [d]$, $\langle t_{u_i}(x), \alpha_{d-j} \rangle = \langle x, \alpha_{d-j} \rangle$.

**Proof.** We have $u_i \in \Lambda_j \subseteq H_{d-j}^1$, therefore $\langle u_i, \alpha_{d-j} \rangle = 0$ and thus
\[ \langle t_{u_i}(x), \alpha_{d-j} \rangle = \langle x + u_i, \alpha_{d-j} \rangle = \langle x, \alpha_{d-j} \rangle + \langle u_i, \alpha_{d-j} \rangle = \langle x, \alpha_{d-j} \rangle + 0. \]

For $i = 1, \ldots, d$ let $(H_i^2)^+ := t_{u_i}((H_i^1)^+)$, and define
\[ Q := \bigcap_{i=1}^d [(H_i^1)^+ \setminus (H_i^2)^+]. \]

**Lemma 87.** The region $Q$ is a fundamental region for the action of $\Lambda$ on $\mathbb{R}^d$.

**Proof.** For $i = 1, \ldots, d$, write
\[ l_i := \langle u_i, \alpha_i \rangle. \]

Then, $Q = \{ x \in \mathbb{R}^d \mid 0 \leq \langle x, \alpha_i \rangle < l_i \text{ for all } i = 1, \ldots, d \}$. It is clear that $Q$ can contain at most one point for each orbit of the action of $\Lambda$.

Now choose and fix an $x \in \mathbb{R}^d$. We want to construct an $y \in Q$ such that $x \in y + \Lambda$.

To this end write $x_0 := x$ and let $\lambda_d := \lfloor \langle x_0, \alpha_d \rangle/l_d \rfloor$. Then let
\[ x_1 := x_0 - \lambda_d u_d, \text{ thus } 0 \leq \langle x_1, \alpha_d \rangle < l_d. \]

For every $i \in \{1, \ldots, d-1\}$ define now recursively $\lambda_{d-i} := \lfloor \langle x_i, \alpha_{d-i} \rangle/l_{d-i} \rfloor$ and $x_{i+1} := x_i - \lambda_{d-i} u_{d-i}$, so that
\[ 0 \leq \langle x_{i+1}, \alpha_{d-i} \rangle < l_{d-i} \]
and so, by Corollary 86, for every $j < i$:
\[ \langle x_{i+1}, \alpha_{d-j} \rangle = \langle t_{-\lambda_{d-i}} \cdots t_{-\lambda_{d-j-1}}(x_{j+1}), \alpha_{d-j} \rangle = \langle x_{j+1}, \alpha_{d-j} \rangle \in [0, l_{d-j}]. \]

After $d$ steps, we will have reached $x_d$, with
\[ 0 \leq \langle x_d, \alpha_i \rangle < l_i \text{ for all } i = 1, \ldots, d. \]

Hence $y := x_d \in Q$ is the required point because, putting $u := \sum_{i=1}^d \lambda_i u_i$, we have by construction $x_d = t_{-u}(x)$ and so $x = t_u(y) \in y + \Lambda$. □

**Definition 88.** Let $\mathcal{A}$ be a rank $d$ toric arrangement, and let $B_d$ be the ‘boolean poset on $d$ elements’, i.e., the acyclic category of the subsets of $[d]$ with the inclusion morphisms.

Since $B_d$ is a poset, the function
\[ \text{Ob}(\mathcal{F}(\mathcal{A})) \to \text{Ob}(B_d), \quad F \mapsto \{ i \in [d] \mid F \subseteq K_i \}, \]
induces a well defined functor of acyclic categories
\[ \mathcal{I} : \mathcal{F}(\mathcal{A}) \to B_d^{op}. \]

For every $I \subseteq [d]$ define the category
\[ \mathcal{F}_I := \mathcal{I}^{-1}(I). \]
Our main technical result about the category $F_I$ is the following.

**Lemma 89.** For all $I \subseteq [d]$, the subcategory $F_I$ is a poset admitting an acyclic matching with only one critical element (in top rank).

We postpone the proof of this lemma after some preparatory steps. Fix $I \subset [d]$, let $k := |I|$.

We consider $Q_I := Q \cap \left( \bigcap_{i \in I} H_i^1 \right) \setminus \bigcup_{j \not\in I} (H_j^1 \cup H_j^2)$.

The set $B := \{H \cap X \mid H \in \mathcal{A}, H \cap Q \neq \emptyset\}$ is a finite arrangement of affine hyperplanes in the affine hull $X$ of $Q_I$. This arrangement determines a (regular) polyhedral decomposition $D(B)$ of $\mathbb{R}^{d-k}$ that coincides with $D(\mathcal{A} \cap X)$ on $Q$.

The covering of Section 2.2.2 maps $Q_I$ homeomorphically to its image, hence $F_I$ is the face category of the set of cells of the decomposition of $Q_I$ by $D(B)$. Regularity of $D(B)$ implies that $F_I$ is a poset. Indeed, if $D(B)^\vee$ is the (regular) CW-decomposition dual to the one induced by $B$, then $F_I^{op}$ is the poset of cells of $Y_I$ (subcomplex of $D(B)$) that is entirely contained in $Q_I$.

Let $Q$ be the subdivision induced by $B$ on the closure $\overline{Q_I}$.

**Lemma 90.** The complex $Q$ is shellable.

**Proof.** Coning the arrangement $B$ (as in [26, Definition 1.15]) we obtain a central arrangement $\hat{B} = \{ \hat{H} \mid H \in B \}$ which subdivides the unit sphere into a regular cell
complex $\mathcal{K}$. Then, $\mathcal{Q}$ is isomorphic to the subcomplex of $\mathcal{K}$ given by

$$\bigcap_{i \notin I} \tilde{H}^1_i \cap \bigcap_{i \notin I} \tilde{H}^2_i$$

which, by [2, Proposition 4.2.6 (c)], is shellable.

**Proof of Lemma 89.** The pseudomanifold $\mathcal{Q}$ is constructible because it is shellable. With [1, Theorem 4.1], it is also endo-collapsible, i.e., it admits an acyclic matching where the critical cells are precisely the cells on the boundary plus one single cell in the interior of $\mathcal{Q}$. But this restricts to an acyclic matching of the subposet $\mathcal{F}_I \subseteq \mathcal{F}(\mathcal{Q})$ with exactly one critical cell.

In turn this gives an acyclic matching of $\mathcal{F}_I^{op}$ with exactly one critical cell. Since $\mathcal{F}_I^{op}$ is the face poset of the CW-complex $Y_I$, the critical cell must be in bottom rank - thus in top rank of $\mathcal{F}_I$, as required.

**Proposition 91.** For any complexified toric arrangement $\mathcal{A}$, the acyclic category $\mathcal{F}(\mathcal{A})$ admits a perfect acyclic matching.

**Proof.** Let $\mathcal{A}$ be of rank $d$. The proof is a straightforward application of the Patchwork Lemma 52 in order to merge the $2^d$ acyclic matchings described in Lemma 89 along the map $I$ of Definition 88. The resulting ‘global’ acyclic matching has $2^d$ critical elements and is thus perfect.

6.2 **Perfect matchings for the toric Salvetti complex**

Let $\mathcal{A}$ be a (complexified) toric arrangement.

**Proposition 92.** The Salvetti Category $\text{Sal} \mathcal{A}$ admits a perfect acyclic matching.

**Proof.** Let the set $\mathcal{Y}$ be totally ordered according to Definition 59. Let $P$ denote the acyclic category given by the $|\mathcal{Y}|$-chain. We define a functor of acyclic categories

$$\varphi : \text{Sal} \mathcal{A} \to P; \quad m \mapsto (Y, C) \text{ for } m \in \mathcal{N}_{(Y, C)}$$

and by Theorem 71 we have an isomorphism of acyclic categories $\varphi^{-1}((Y, C)) = \mathcal{N}_{(Y, C)} \simeq \mathcal{F}(\mathcal{A}^Y)^{op}$. Then, by Proposition 91, $\varphi^{-1}((Y, C))$ has an acyclic matching with $2^d - \text{rk}_X$ critical cells.

An application of the Patchwork Lemma 52 yields an acyclic matching on $\text{Sal}(\mathcal{A})$ with

$$\sum_j |\mathcal{Y}_j| 2^{d-j} = \sum_j |\mathcal{A}_j| 2^{d-j} = P_{\mathcal{A}}(1)$$

critical cells, where the first equality is given by Lemma 58. This matching is thus perfect.

**Corollary 93.** The complement $M(\mathcal{A})$ is a minimal space.
Proof. The cellular collapses given by the acyclic matching of Proposition 92 show that the complement $M(\mathcal{A})$ is homotopy equivalent to a complex whose cells are counted by the Betti numbers. □

**Corollary 94.** The homology and cohomology groups $H_k(M(\mathcal{A}), \mathbb{Z})$, $H^k(M(\mathcal{A}), \mathbb{Z})$ are torsion free for all $k$.

*Proof.* See in Corollary 14. □

7 Application: minimality of affine arrangements

After the existence proofs of Dimca and Papadima in [14] and by Randell in [27], the first step towards an explicit characterization of the minimal model for complements of hyperplane arrangements was taken by Yoshinaga [32] who, for complexified arrangements, identified the cells of the minimal complex using their incidence with a general position flag in real space and studied their boundary maps. Salvetti and Settepanella [31] obtained a complete description of the minimal complex by using a ‘polar ordering’ determined by a general position flag to define a perfect acyclic matching on the Salvetti complex.

In this section we explain how to use our techniques in order to extend to affine complexified hyperplane arrangements the idea of [12]. We thus obtain a minimal complex that is defined only in terms of the arrangement’s (affine) oriented matroid and is less cumbersome than the one described in [13].

Consider a finite affine complexified arrangement $\mathcal{A} = \{K_1, \ldots, K_n\}$. Define the central arrangements $\mathcal{A}_0$ and $\mathcal{A}[F]$ for $F \in \mathcal{F}(\mathcal{A})$ in analogy to those of Section 4.1. Choose a base chamber $B \in \mathcal{T}(\mathcal{A}_0)$, fix a total ordering $\prec_0$ on $\mathcal{A}_0$ and define $\prec_F$, $\prec_Y$ for $F \in \mathcal{F}(\mathcal{A}), Y \in \mathcal{L}(\mathcal{A})$ as in Section 4.1. Moreover, let $\mathcal{Y}$ be as in Definition 56.

**Remark 37.** Notice that, given the affine oriented matroid of $\mathcal{A}$, the oriented matroid of $\mathcal{A}_0$ can be recovered without referring to the geometry. For instance, the tope poset of $\mathcal{A}_0$ can be defined in terms of the tope poset of $\mathcal{A}$ based at any unbounded chamber.

**Lemma 95.** Let $\mathcal{A}$ be a finite complexified affine hyperplane arrangement, and $\mathcal{Y}$ as above, then

$$|\mathcal{Y}| = \sum_{k \in \mathbb{N}} \text{rk} H^k(M(\mathcal{A}); \mathbb{Z}).$$

*Proof.* As in Lemma 58, applying [12, Lemma 4.18 and Proposition 2], for all $Y \in \mathcal{L}(\mathcal{A})$ we have

$$|\{C \in \mathcal{T}(\mathcal{A}[Y]) \mid X(Y, C) = Y\}| = \text{rk} H^{\text{codim} Y}(M(\mathcal{A}_Y); \mathbb{Z}).$$

The claim follows with Theorem 15. □

We now define the analogue of the map $\theta$ of Definition 67.

**Definition 96.** Let $F, G \in \mathcal{F}(\mathcal{A})$ with $F \leq G$ and identify

$$\mathcal{A}[F] = \mathcal{A}_F = \{H \in \mathcal{A} \mid F \subseteq H\},$$

in particular we have an inclusion $\mathcal{A}[G] \subseteq \mathcal{A}[F]$ and, correspondingly, a function $i_{F \leq G} : \mathcal{F}(\mathcal{A}[G]) \to \mathcal{F}(\mathcal{A}[F])$ as in Definition 64, which induces a function $j_{F \leq G} : \text{Sal}(\mathcal{A}[F]) \to \text{Sal}(\mathcal{A}[G])$ as in Definition 77.
Theorem 97 (Lemma 3.2.8 and Theorem 4.2.1 of [11]). The assignment \( \mathcal{E} : \mathcal{F}(\mathcal{A}) \to \mathcal{AC}^{\text{op}}, \mathcal{E}(F) := \text{Sal}(\mathcal{A}[F]), \mathcal{E}(F \leq G) := j_{F \leq G} \) defines a diagram of posets such that colim \( \mathcal{E} \) is poset isomorphic to \( \text{Sal}(\mathcal{A}) \).

The stratification of \( \text{Sal}(\mathcal{A}) \) is also defined along the lines of the preceding sections.

Definition 98. Define the map \( \theta : \text{Sal}(\mathcal{A}) \to \mathcal{Y} \) as follows
\[
\theta([F, C]) = (X(F, i_{F \leq G}(G)) \sigma_{\mathcal{A}[X(F, i_{F \leq G}(G))]}(G)).
\]
where we identified \( G = \min \mathcal{L}(\mathcal{A}[G]). \)

Definition 99. Let \( \mathcal{A} \) be a finite complexified affine hyperplane arrangement and define a total ordering \( \preceq \) on \( \mathcal{Y} \) as in Definition 59. Define:
\[
\mathcal{S}_{(Y, C)} = \left\{ [F, C] \in \text{Sal}(\mathcal{A}) \mid \begin{array}{l}
\text{there is } [G, K] \in \text{Sal}(\mathcal{A}) \text{ with } \\
[F, C] \leq [G, K] \text{ and } \theta([G, K]) = (Y, C)
\end{array} \right\}
\]
\[
\mathcal{N}_{(Y, C)} = \mathcal{S}_{(Y, C)} \setminus \bigcup_{(Y', C') \prec (Y, C)} \mathcal{S}_{(Y', C')},
\]

The arguments of Section 5 can now be adapted to the affine case, obtaining the following analogon of Theorem 71.

Theorem 100. Let \( \mathcal{A} \) be a finite complexified affine hyperplane arrangement. There is an isomorphism of posets
\[
\mathcal{N}_{(Y, C)} \cong \mathcal{F}(\mathcal{A}[Y])^{\text{op}} \quad \text{for all } (Y, C) \in \mathcal{Y}.
\]

The analogon of Proposition 91 is proved in [2, Theorem 4.5.7 and Corollary 4.5.8], from which it follows that the poset \( \mathcal{N}_{(Y, C)}^{\text{op}} \) is shellable, and therefore \( \mathcal{N}_{(Y, C)} \) admits an acyclic matching with one critical cell in top dimension. Applying the Patchwork Lemma as in Proposition 92 we obtain a perfect acyclic matching \( \mathcal{M} \) of \( \text{Sal}(\mathcal{A}) \). We summarize.

Proposition 101. Let \( \mathcal{A} \) be a finite complexified affine hyperplane arrangement. The (affine) oriented matroid data of \( \mathcal{A} \) intrinsically define a discrete Morse function on \( \text{Sal}(\mathcal{A}) \) that collapses the Salvetti complex to a minimal complex.

Remark 38. The considerations of this section carry over to the general case of non-stretchable affine oriented matroids, as in [12] for the non-affine case.
