Basée à Porrentruy, la Paléontologie A16 est financée par l'Office fédéral des routes (OFROU) et par la République et Canton du Jura. Sa mission se concentre sur le tracé A16 de 24,675 km de long, comprenant les sections autoroutières situées entre Boncourt et Porrentruy, ainsi qu'entre Delémont et Choindez. Sa mission principale consiste à documenter les nombreuses découvertes mises au jour et l'exploitation scientifique des données, la gestion de la documentation et des collections ainsi que la transmission de l'ensemble de cet héritage à la République et Canton du Jura.

Charophyte: *Rantzieniella nitida*
Foraminifère: *Protelphidium nonioninoides*

Avant-propos

Basée à Porrentruy, la Paléontologie A16 est un projet pilote de paléontologie autoroutière, financé à hauteur de 95% par l'Office fédéral des routes et de 5% par la République et Canton du Jura. Sa mission, de 2000 à 2018, se concentre sur le tracé de la route nationale A16 Transjurane, long de 24,675 km. La Paléontologie A16 a prospecté et fouillé 64 sites des sections autoroutières 1, 2, 3, 7 et 8 entre Boncourt et Porrentruy – principalement sur le plateau de Courtedoux – ainsi qu'entre Delémont et Choindez. Les découvertes paléontologiques sont le fruit de cette activité de terrain de grande envergure, avec des fouilles contrôlées menées de 2005 à 2011, grâce au soutien financier conséquent de l'Office fédéral des routes. La mission principale de la Paléontologie A16 consiste à sauvegarder ces nombreuses découvertes, à les documenter, les gérer en collection, les exploiter scientifiquement et, finalement, transmettre l'ensemble de cet héritage à la République et Canton du Jura.

Dans ce cadre, les *Catalogues du patrimoine paléontologique jurassien–A16* ont été créés sur une idée originale de Wolfgang A. Hug, responsable de l'équipe Paléontologie A16 de 2002 à 2016. Ils sont réalisés par la Paléontologie A16 et publiés sous les auspices de l'Office de la culture de la République et Canton du Jura.

Le but de ces catalogues est de présenter les principales découvertes paléontologiques A16 et leur documentation exhaustive et inédite, en particulier pour les sites à traces de dinosaures. Ils accompagnent ainsi l'inventaire de la collection physique de la Paléontologie A16 et ses quelque 65 000 objets répertoriés (fossiles, sédiments, minéraux, etc.). De plus, en facilitant l'accès à une sélection d'objets phares, ces catalogues sont une porte d'entrée vers les découvertes paléontologiques A16 pour la communauté scientifique. La diffusion de la série complète des catalogues en format papier est limitée, mais une version électronique est disponible en ligne et en libre accès.

Les thèmes couverts par les catalogues correspondent aux principales études menées par la Paléontologie A16. Les couches géologiques de trois grandes périodes traversées par l'A16 ont déterminé la nature des découvertes et donc des études. Pour le Mésozoïque, il s'agit en particulier des traces de dinosaures, des vertébrés et des invertébrés marins mis au jour dans les calcaires et les marnes du Jurassique supérieur (Oxfordien et Kimméridgien). Pour le Cénozoïque, il s'agit essentiellement des faunes de mammifères et de microfossiles de la Molasse (Éocène, Oligocène et Miocène) et des faunes de mammifères des dolines à la fin du Cénozoïque (Pléistocène).

Les données cataloguées sont présentées de manière synthétique, synoptique et richement illustrée (fossiles, localités, coupes géologiques, méthodologie de fouille, etc.). Les coordonnées spatiale et temporelle de chaque objet sont précisément indiquées; la détermination de chaque fossile reste fonction de l'état actuel des connaissances. Les catalogues documentent aussi certaines analyses menées, sous forme de mandats, par des instituts externes.

Les *Catalogues du patrimoine paléontologique jurassien–A16* sont le reflet de la devise de la Paléontologie A16: Sauvegarder, Étudier, Transmettre. Qu'ils soient utiles pour la mémoire de cette activité unique, pour de futures études scientifiques et pour la gestion pérenne de ce patrimoine – d'importance nationale –, dont la responsabilité incombe à la République et Canton du Jura.

Merci à toutes les collaboratrices et à tous les collaborateurs de l'équipe de la Paléontologie A16 : ces catalogues constituent un bel aboutissement de votre engagement.

1 Introduction

This catalogue documents the three most common groups of microfossils from the Cainozoic sediments of the Canton of Jura exposed by the construction of Highway A16. Microfossils represent remains of biota generally smaller than 1 mm. Accordingly the catalogue is organized in three parts, illustrating 10 species of Charophyta, 48 taxa of Foraminifera and 30 taxa of Ostracoda on 78 plates and 29 text-figures. Information on ostracod taxa is supplemented by spatiotemporal distribution maps and measurement tables.

The occurrences of not individually described taxa of Charophyta, reworked benthic Foraminifera and planktonic Foraminifera are grouped cumulatively in tables. The results of small mammal teeth have been published separately (Prieto et al. 2018; Maridet et al., in prep.).

Taxonomy of ostracods, foraminifers and charophytes follows the literature respectively outlined in Pirkenseer & Berger (2011), Pippèrr (2015) and Mojon et al. (2018).

Charophyta

Charophyta are an extant group of multicellular green algae generally living in carbonate-rich, oligotrophic ponds and lakes as well as less frequently in brackish waters (e.g. Zeneli & Kashta 2016). The fossil record of charophytes reaches back into the Palaeozoic Era (e.g. Kelman et al. 2007). The most commonly preserved parts of charophytes are calcified stems and oogonia. Oogonia represent female reproductive organs of stoneworts, which are commonly found in lacustrine marls and siltstones of the Swiss Molasse Basin. Due to a comparatively rapid morphological evolution of charophyte oogonia a biostratigraphic framework based on assemblages zones complements the standard Cainozoic mammal biozonation (ELMMZ) for European non-marine sediments (Berger 1999; Mojon et al. 2018).

In the Canton of Jura charophyte oogonia have been mainly documented from late Rupelian to Aquitanian fluvial and lacustrine sediments of the "Molasse alsacienne" and the "Calcaires delémontiens".

The most common occurrence of oogonia adheres to the lower part of the "Molasse alsacienne", denoting the middle to late Rupelian non-basal *Rhabdochara major*-zone (for details on assemblage zones see Mojon et al. 2018) for the localities POI / PRC / VEG / PCA / BIR / BEU / BEE / EPN, CLU, LGR, CLM / VRG / RIN / CTR in the Delémont Basin and ETA in the Ajoie. The cumulative regional charophyte assemblage includes the taxa *Rhabdochara* gr. *stockmansi-major*, *Rhabdochara* gr. *praelangeri-major*, *Nitellopsis* (*Tectochara*) gr. *meriani*, *Gyrogona medicaginula*, *Gyrogona wrighti*, *Gyrogona caelata*, *Sphaerochara* gr. *hirmeri* and *Chara minutissima*.

The subsequent *Chara microcera*-zone attributes part of the Molasse alsacienne at the locality EPN to the late Rupelian to early Chattian stages.

The youngest charophyte assemblage from the "Calcaires delémontiens" including *Rantzieniella nitida*, *Stephanochara* gr. *praeberdotensis*, *Nitellopsis* (*Tectochara*) gr. *meriani*, *Chara* gr. *molassica-notata*, *Sphaerochara* gr. *hirmeri* pertaining to the *Rantzieniella nitida*-zone correlates the locality MCX in the central Delémont Basin to the Aquitanian stage.

Foraminifera

Foraminifera form an extant, extremely diverse group of unicellular Eukaryotes that – with only few exceptions – build shells ("tests") and live in marine environments. The fossil record reaches at least back into the early Cambrian (earliest Palaeozoic Era) (e.g. Culver 1991; Pawłowski et al. 2003). Foraminifera are characterized by two basic test morphologies, either built of CaCO_3 (plate 7-37) or agglutinated detrital grains (see plate 1-6, 38/fig. 1-5) of various origins. Foraminifera adhere to two modes of life, either living on or in the sea floor ("benthic") or drifting in the upper part of the water column ("planktonic").

Planktonic Foraminifera are instrumental for the biostratigraphy (relative age of sediment strata) of Cretaceous and Cainozoic

(e.g. P-O zones in Berggren & Pearson 2009) marine sediments due to their high rates of evolution and global distribution. Benthic Foraminifera assemblages and key species are characteristic for discrete marine habitats and incorporate related chemical properties of the surrounding seawater. Fossil benthic Foraminifera and the chemical composition of their tests thus allow reconstructions of past environmental conditions (e.g. water depth, oxygenation and salinity amongst many others).

The Foraminifera from Rupelian marine deposits ("Septarienton") of the Canton of Jura mainly consist of benthic species. Planktonic Foraminifera are rare and generally poorly preserved, which is to be expected in nearshore environments experiencing increased influx of coarser clastic sediments.

Autochthonous inner neritic or lagoonal low-diversity benthic Foraminifera assemblages from localities closest to the palaeo-coast (OIS, ETA, BEE) are dominated by taxa like *Quinqueloculina* spp., *Pararotalia canui*, *Aubignyna kiliani* and *Buccella* spp. Assemblages including *Cancris subconicus*, *Cibicidoides* spp., *Melonis* spp., *Bolivina* spp. are documented for the localities RNA and CHM, indicating slightly more offshore, well-oxygenated inner to outer neritic palaeoenvironments.

The poorly preserved, abundant benthic Foraminifera from the basal fluvial "Molasse alsacienne" represent reworked specimens from older regional, characteristic "Meeressand" assemblages (e.g. in Pirkenseer et al. 2010), indicated by the exclusive occurrence of well-sorted, large and thick-shelled calcitic or massive agglutinated forms bearing imprints and abrasions from quartz grains. Rare large, reworked planktonic Foraminifera and some specimens of allochthonous larger benthic Foraminifera (LBF) of Cretaceous and Eocene age co-occur. Their highly abraded and fragmented state indicates a protracted fluvial transport from alpine source sediments (e.g. Pirkenseer et al. 2011).

The scarcity of the material, the poor preservation and the absence of index taxa of planktonic Foraminifera unfortunately hampers a biostratigraphic interpretation of the marine sediments.

Ostracoda

Ostracods, commonly called mussel or seed shrimps represent a class within the subphylum of Crustacea (e.g. crabs, shrimps, woodlice). Ostracods typically are crustaceans smaller than 1 mm, their body being protected by a bivalved, hinged carapace (hence the common name). The oldest true ostracods date back to the early Ordovician period (e.g. Williams et al. 2008).

Ostracods live in deep-sea to freshwater habitats and even in moist soils (Harding 1953). During their life cycle ostracods develop nine consecutive moult stages (eight juvenile, one adult) of increasing size. Ostracods live mainly on or in the sediment, while pelagic planktonic taxa are rare. Ostracods, with few exceptions, do not tolerate reduced oxygenation levels, hence they are not recorded from dysoxic sediments. Individual ostracod taxa are sensible towards environmental changes, especially salinity

gradients, water temperature or depth. Distinct shifts in ostracod assemblage composition can accordingly be assigned to changes in e.g. palaeosalinity.

Ostracods occur in the fossil record either as closed carapaces, or as individual valves (more common). A predominance of closed carapaces and the presence of many moults stages hint towards an autochthonous assemblage, whereas a majority of valves (often sorted by size) indicate at least local post-mortem transport. Separate valves however are easier to determine, since internal features of the shell (e.g. hinge structure, muscle scars) are often taxonomically distinct.

The Ostracoda of the Canton of Jura are mainly recorded from Rupelian marine ("Septarienton") to deltaic ("Marnes à Cyrènes") sediments. Freshwater ostracods from the subsequent fluvatile "Molasse alsaciennne" are exceedingly rare. The quick shift from (e.g. localities COM, RNA) or the co-occurrence of (e.g. localities BEE, ETA) shallow marine to coastal assemblages (e.g. *Legumino-cythereis sorneana*, *Loxoconcha* spp., *Cytheridea sandbergeri* and *Cytheretta* spp.) to / and brackish, deltaic assemblages dominated by *Hemicyprideis helvetica* indicate a rapid desalination of the shallow Delémont Basin and the Ajoie region in the late Rupelian as well as repeated short-term shifts of palaeoenvironments in the context of a prograding river delta system (e.g. Pirkenseer et al. 2018).

Material and sample numbering system

The material is stocked following a consecutive numbering scheme based on the year of sampling and the sample locality (and **not** section and sample depth), partly grouping lots of microfossils, partly discerning individually figured specimens. Closely related specimen or lot sample numbers **do not** necessarily represent the same sample level and /or the same section.

Several discrete, sometimes strongly diverging numbers are due to non-consecutive preparation, selection or grouping of picked specimens and different sampling years and may be derived from an individual **initial sediment sample** (or several from a same sample depth at a given section, see example below). Accordingly these numbers are grouped for each described taxon under their initial sediment sample(s) and referenced to the relevant locality, unit (=individual section) and layer (=sampling depth) for the convenience of the reader.

Example (under "Occurrences", *Cytheridea sandbergeri*, p. 148): Picking cell numbers BEE006-34 / BEE004-165 to 167 / BEE003-557, 860 to 861, 970 (note different sampling years!) pertain to the initial respective sample numbers 1/260/767, all derived from the same layer 1800 of unit (section) 19 of the locality BEE.

Synonymy

Genus *Spiroplectinella* Kisel'man, 1972Type species: *Spirolecta wightii* Silvestri, 1903, 1913*Spiroplectinella deperdita* (d'Orbigny, 1846)

- * 1846 *Textularia deperdita* – d'Orbigny, p. 244, pl. 14, fig. 23-35
- partim 1958 *Spiroplectammina carinata* – Batjes, p. 98, pl. 1, fig. 3, [non 2]
- 1974 *Spiroplectammina deperdita* – Doebl & Sonne, p. 15, pl. 1, fig. 1
- 1987 *Textularia deperdita* – Reiser, p. 59, pl. 2, fig. 4-5
- 1994 *Spiroplectinella deperdita* – Grimm, pl. 1, fig. 11, pl. 2, fig. 4
- 1998 *Semivulvulina deperdita* – Cicha et al., p. 126, pl. 5, fig. 11
- 2003 *Spiroplectinella deperdita* – Becker, pl. 8, fig. f
- 2004 *Spirorutilus deperditus* – Schudack & Nuglisch, p. 74, pl. 6, fig. 103-104
- 2006 *Spirorutilus deperditus* – De Man, p. 260, pl. 1, fig. 11-13
- 2010 *Spiroplectinella carinata* – Pirkenseer et al., pl. 2, fig. 12
- 2011 *Semivulvulina deperdita* – Havran, pl. 8, fig. 1

Remarks

Batjes (1958) mentions the occurrence of transitional morphs leading to a *Spiroplectinella carinata* habitus. In general *Spiroplectinella deperdita* is much thicker (e.g. specimen in Doebl & Sonne 1974) in peripheral view, smaller on average with nearly horizontal sutures and lacks carinae. While initially both species show a fast increase in width (in microspheric forms), mature *Spiroplectinella carinata* specimens develop nearly parallel carinae (see specimens figured in Pirkenseer et al. 2010). We follow Grimm (1993, 1994) in the generic assignment of the species (presence of pseudopores, rhombical cross section, planispiral initial whorl).

Material

at least 31 specimens (RNA987)

at least 574 specimens as *Cycloforina* spp. (due to poor preservation, locality BEE)

Synonymy

Genus *Cycloforina* Łuczkowska, 1972

Type species: *Quinqueloculina contorta* d'Orbigny, 1846

Cycloforina impressa (Reuss, 1851)

- * 1851 *Quinqueloculina impressa* – Reuss, p. 87, pl. 7, fig. 59
- partim 1884 *Quinqueloculina impressa* – Andreæ, p. 155, 225, pl. 10, fig. 25, 27, [non 26]
- ? 1958 *Quinqueloculina impressa* – Batjes, p. 103, pl. 1, fig. 13
- 1974 *Quinqueloculina impressa subovalis* – Doebl & Sonne, p. 15, pl. 1, fig. 2
- 2004 *Quinqueloculina laevigata* – Gebhardt, p. 261, fig. 14/6-7
- 2004 *Quinqueloculina laevigata* – Grimm, p. 68, pl. 1, fig. 1
- 2007 *Quinqueloculina akneriana* – Schudack & Nuglisch, p. 14, pl. 10, fig. 12
- non 2008 *Cycloforina impressa* – Picot et al., pl. 1, fig. 6-7

Remarks

Schudack & Nuglisch (2007) discuss the synonymy of *Quinqueloculina akneriana* and *Q. impressa* and assign the latter to the former species, disregarding however the pronounced size difference (*Q. akneriana* is much larger) and the cycloforine aperture of *Q. impressa*. Accordingly we maintain the validity of *Q. impressa* and assign the species to the genus *Cycloforina* Łuczkowska, 1972. Juveniles of other quinqueloculinid species may be confused with adult *Cycloforina impressa* (Łuczkowska 1972).

The poorly preserved specimens from site Beuchille-Est (mainly moulds) may either belong to *Cycloforina hauerina* d'Orbigny, 1846, *C. ludwigi* Reuss, 1866 or *C. impressa*.

Synonymy

Genus *Glandulina* d'Orbigny, 1839

Type species: *Nodosaria (Glandulina) laevigata* d'Orbigny, 1826

Glandulina ovula d'Orbigny, 1846

- * 1846 *Glandulina ovula* – d'Orbigny, p. 29, pl. 1, fig. 6-7
- 1857 *Glandulina candula* nov. spec. – Egger, p. 304, pl. 15, fig. 28-29
- 1863 *Glandulina elliptica* – Reuss, p. 47, pl. 3, fig. 29-31
- 1974 *Glandulina ? laevigata inflata* – Doebl & Sonne, p. 25, pl. 6, fig. 40
- 1985 *Glandulina ovula* – Papp & Schmid, p. 21, pl. 2, fig. 1-9
- 1987 *Glandulina ovula* – Wenger, p. 266, pl. 6, fig. 15-16
- 1998 *Glandulina ovula* – Cicha et al., p. 98, pl. 29, fig. 6
- 2007 *Glandulina ovula* – Schudack & Nuglisch, p. 20, pl. 3, fig. 57-58

Glandulina aequalis Reuss, 1863

- * 1863 *Glandulina aequalis* – Reuss, p. 48, pl. 3, fig. 28
- 1958 *Glandulina aequalis* – Batjes, p. 123, pl. 4, fig. 5-6
- 1970 *Glandulina aequalis* – Le Calvez, p. 99, fig. 35
- 1974 *Pseudonodosaria ? aequalis* – Doebl & Sonne, p. 19, pl. 2, fig. 11
- ? 1974 *Glandulina ex gr. reussi* – Doebl & Sonne, p. 26, pl. 6, fig. 42
- 1987 *Glandulina aequalis* – Reiser, p. 76, pl. 6, fig. 9

Remarks

When reviewing the literature (e.g. Papp & Schmid 1985) and the available material the presence of a wide variety of intermediate forms between both species (and the recent *Glandulina laevigata* (d'Orbigny 1826) becomes apparent. Our material only contains macrospheric specimens with well-rounded basal end.

- 1987 *Brizalina beyrichi* – Huber, p. 74, pl. 5, fig. 6-9
- 1998 *Bolivina beyrichi beyrichi* – Cicha et al., p. 83, pl. 44, fig. 3
- 2000 *Bolivina beyrichi* – Mehrnusch, p. 223, pl. 1, fig. 1-8, pl. 2, fig. 1-8
- 2010 *Bolivina beyrichi* – Pirkenseer et al., p. 14, pl. 7, fig. 3-4

Remarks

On average larger than *Bolivina versatilis* and *B. melettica* (identical scale applied to all species of *Bolivina*). The former shows straighter sutures and a more contorted test, the latter features regularly arched sutures, more inflated chambers and no lateral carinae. Poorly preserved specimens are difficult to separate from *Bolivina melettica*.

Remarks

Fossil and extant species of *Cibicides* and *Cibicidoides* are in need of a thorough revision. As has been discussed in Schweizer et al. (2009) a morphological attribution to each genus or species is rendered difficult or arbitrary in light of results from molecular phylogeny, due to the existence of a high morphological variability in single genetic species and the presence of cryptic taxa. Since external morphology in cibicidids is driven by their mode of life (attached to substrate and/or free-living) the validity of their former generic (e.g. sensu Loeblich & Tappan 1988) and specific subdivision needs to be re-evaluated for fossil morphospecies.

Our material adheres to three morphogroups:

- *Cibicidoides* sp. 1 represents small-sized (200-300 µm max. D) planoconvex keeled specimens featuring about 8-10 chambers in the outer whorl, subdivided by strongly curved sutures, an imperforate umbilical and lateral side as well as a closed umbilicus (leading to a subconical lateral view).
- The *Cibicidoides lobatulus* (Walter & Jacob 1798 [recent]) - *communis* (Roemer 1838 [fossil]) morphogroup includes specimens of highly variable sizes ranging between 250 to 700 µm (or larger, see Pirkenseer et al. 2010, "*Cibicidoides roemeri*") maximal diametre. Small individuals are generally planoconvex to concavoconvex, while larger specimens are generally slightly biconvex. Final chambers are generally strongly inflated in all sizes, with only the youngest chambers featuring a sharp keel, whereas in older chambers the keel is indistinct. Individuals bear perforations on the entire test except for the area around the aperture and on the keel. Sutures on the umbilical side are straight.
- *Cibicidoides* sp. 2 comprises distinctly biconvex keeled medium-sized specimens with an occluded apical side.

To illustrate the morphological and size variation all specimens are figured to the same scale on plate 1 and 2. Small-sized individuals are figured additionally at a larger scale for more details on plate 3 and 4. Most specimens are derived from closely spaced samples of drillcore RNA-F1 (except for RNA987-116). Specimens from the localities PCA, POI, SOL and VEG are presumed to be reworked from older strata and thus generally uncertain of even generic affiliation.

Material

122 specimens, 2 specimens uncertain

Remarks

We follow the discussion in Wenger (1987) concerning the retention of the genus *Protelphidium* (based on the presence of "open intercameral sutures"), but agree that the generic definitions of *Nonion* and *Protelphidium* remain uncertain. In *Nonion* the chambers generally increase size at a higher rate, are more inflated and ovoid/elongated in apertural view, with the umbilical granulation reaching into the less depressed umbilical part of the sutures.

The similar *Protelphidium roemerii* (Cushman 1936) potentially represents a junior synonym of *P. nonioninoides*.

Material

at least 72 specimens, 4 specimens uncertain; at least 131 specimens as *Gyroidinoides/Hansenisca* indet.

Synonymy

Genus *Hansenisca* Loeblich & Tappan, 1988
Type species: *Gyroidina soldanii* d'Orbigny, 1826
Hansenisca soldanii (d'Orbigny, 1826)

- * 1826 *Gyroidina soldanii* – d'Orbigny, p. 278
- 1846 *Rotalina soldanii* – d'Orbigny, p. 155, pl. 8, fig. 10-12
- 1958 *Gyroidina soldanii* – Batjes, p. 147, pl. 7, fig. 12-15
- 1987 *Gyroidina soldanii* – Reiser, p. 101, pl. 12, fig. 7, 10-11
- 1994 *Hansenisca soldanii* – Grimm, p. 86, pl. 2, fig. 9
- 1998 *Hansenisca soldanii* – Cicha et al., p. 105, pl. 72, fig. 6-8
- 1998 *Hansenisca soldanii* – Rögl, p. 146, pl. 6, fig. 4-5
- 2005 *Gyroidina soldanii* – Rasmussen, p. 106, pl. 17, fig. 12-14
- 2005 *Hansenisca soldanii* – Schudack & Nuglisch, p. 79, pl. 10, fig. 196-197
- 2006 *Hansenisca soldanii* – de Man, p. 300, pl. 15, fig. 7
- non2010 *Gyroidina soldanii* – Margreth, p. 125, pl. 40, fig. 1
- 2010 *Gyroidina neosoldanii* – Margreth, p. 125, pl. 40, fig. 2
- 2010 *Hansenisca soldanii* – Pirkenseer et al., pl. 11, fig. 4

Remarks

Poorly preserved specimens are difficult to attribute either to *Hansenisca* or *Gyroidinoides*, since both feature open umbilici and potentially apertural flaps. *Gyroidina* sensu Loeblich & Tappan (1988) features a closed umbilicus. Variations in spiral height, grade and kind of spiral curvature as well as peripheral angularity complicate specific assignment.

- * 1928 *Rotalia canui* nom. nov. – Cushman, p. 55, pl. 3, fig. 2
- 1957 *Pararotalia curryi* – Loeblich & Tappan, p. 13, pl. 3, fig. 5-7
- ?partim 1958 *Pararotalia canui* – Batjes, p. 168, pl. 12, fig. 5-6, [??]
- 1960 *Pararotalia canui* subsp. *rhenana* – Ellermann, p. 688, pl. 54, fig. 7
- 1987 *Pararotalia canui* – Reiser, p. 105, pl. 14, fig. 1-3
- 1998 *Pararotalia canui* – Cicha et al., p. 116, pl. 73, fig. 11-13
- 2005 *Pararotalia curryi* – Schudack & Nugisch, p. 79, pl. 11, fig. 209
- 2010 *Pararotalia canui* – Pirkenseer et al., p. 17, pl. 11, fig. 9

Remarks

We follow the discussion in Reiser (1987) concerning the specific assignment of *Pararotalia canui*, since Cushman (1928) attributed unrelated new material from the Rupelian of the Paris Basin to *Rotalia stellata* Reuss from the Chattian of northern Germany, 1855 while providing a new name (under assumption of precedence of *Rotalia stellata* Ehrenberg, 1840). Accordingly *Pararotalia curryi* Loeblich & Tappan, 1957 is put into synonymy, and Cushman's specimens becoming the holotypes for *P. canui*. We however agree with Loeblich & Tappan (1957) with the uncertain status of *Rotalia stellata* sensu Reuss (1855), which probably represents a different larger species lacking spines and featuring an acute periphery. Our material shows a wide variety of morphologies (all figured specimens are derived from the same sample), ranging from lobate forms with inflated chambers to stellate specimens with angular periphery. An umbilical plug is not always preserved.

SynonymyGenus *Elphidium* Montfort, 1808Type species: *Nautilus macellum* Fichtel & Moll, 1798*Elphidium crispum* (Linnaeus, 1758)

- * 1758 *Nautilus crispus* – Linnaeus, p. 709
- 1846 *Polystomella crispa* – d'Orbigny, p. 125, pl. 6, fig. 9-14
- 1857 *Polystomella crispa* – Egger, p. 303, pl. 15, fig. 1-2
- 1987 *Elphidium crispum* – Wenger, p. 289, pl. 11, fig. 14, 18
- 1998 *Elphidium crispum* – Cicha et al., p. 95, pl. 75, fig. 16-17
- 2003 *Elphidium crispum* – Becker, pl. 8, fig. a
- 2005 *Elphidium crispum* – Rasmussen, p. 109, pl. 19, fig. 4
- 2011 *Elphidium [crispum]* – Havran, pl. 7, fig. 1 [species name not indicated on plate, but core log]

Remarks

All specimens are recorded from non-marine strata of the Montchaibeux Member (Bois de Raube Formation) overlying the partially eroded sediments of the OMM (Upper Marine Molasse, for stratigraphy see e.g. Prieto et al. 2018) and are thus reworked.

FORAMINIFERA
allochthonous benthic Foraminifera
(bmainly redeposited in the basal Molasse alsacienne s.l.)

Taxonomy

Phylum	Order	Family	Genus	Species
Foraminifera	various	various	various	various

Determination (name/date): Martina Pippèrr/27.10.2015; Claudius Pirkenseer/12.12.2017

Stratigraphy

Lithostratigraphy	Biostratigraphy	Chronostratigraphy
Molasse alsacienne s.l.	MP 24	Oligocene/Late Rupelian

Occurrences (localities)

Name	Coordinates CH
Courrendlin - Pécas (CRD-PCA)	595 690/243 390
Courrendlin - Poillat (CRD-POI)	594 650/244 600
Courrendlin - Pré Chevalier (CRD-PRC)	594 700/243 560
Courrendlin - Vieille Église (CRD-VEG)	595 395/244 270

Material

CRD-PCA: at least 330 specimens/CRD-POI: at least 1244 specimens/CRD-PRC : at least 22 specimens/CRD-VEG : at least 51 specimens

Remarks

Most calcareous specimens are very poorly preserved and bear quartz grain imprints (see plates). Material is mainly reworked from underlying "Meeressand" deposits (faunal overlap, see autochthonous assemblages in e.g. Huber 1994, Pirkenseer et al. 2010) and redeposited in the basal "Molasse alsacienne s.l." (late Rupelian) localities CRD-POI/PRC/VEG. Few taxa (e.g. *Elphidium crispum* from locality CRD-PCA) are possibly derived from completely eroded local OMM sediments and mixed with older material and redeposited in the Montchaibeux Member (Miocene).

Stratigraphy

Lithostratigraphy	Biostratigraphy	Chronostratigraphy
Molasse alsacienne s.l.	MP 24	Oligocene/Late Rupelian

Occurrences (localities)

Name	Coordinates CH
Courrendlin - Poillat (CRD-POI)	594 650/244 600
Courrendlin - Vieille Église (CRD-VEG)	595 395/244 270
Delémont - Beuchille (DEL-BEU)	593 125/244 580

Remarks

In contrast to reworked Late Cretaceous and Eocene planktic Foraminifera allochthonous Larger Benthic Foraminifera are not known from the late Rupelian and early Chattian of the Upper Rhine Graben. The larger size and weight might explain their shorter transport distance (just reaching the southernmost Upper Rhine Graben). A provenance from the Helveticum is most likely, since in some samples reworked alpine planktic Foraminifera co-occur. A detailed study based on thin sections is required in order to pinpoint the taxonomy of the strongly abraded specimens. The material has been preliminarily attributed to a "amphisteginid", "asterocylinid" and "nummulitic" habitus.

FORAMINIFERA

allochthonous Cretaceous and Eocene planktic Foraminifera
(redeposited in the basal “Molasse alsacienne s.l.”)

Taxonomy

Phylum	Order	Family	Genus	Species
Foraminifera	Rotaliida	various	various	various

Determination (name/date): Claudio Pirkenseer 12.12.2017

Stratigraphy

Lithostratigraphy	Biostratigraphy	Chronostratigraphy
Molasse alsacienne s.l.	MP 24	Oligocene/Late Rupelian

Occurrences (localities)

Name	Coordinates CH
Courrendlin - Poillat (CRD-POI)	594650/244600
Courrendlin - Pré Chevalier (CRD-PRC)	594700/243560

Material

CRD-POI: approx. 177 planktic specimens (may also include poorly preserved Oligocene planktic Foraminifera)/CRD-PRC : at least 3 specimens

Remarks

Reworked Late Cretaceous and Eocene planktic Foraminifera are known from the late Rupelian and early Chattian of the entire Upper Rhine Graben (Fischer 1965; Schäfer 2000; Schäfer & Kuhn 2004; Grimm et al. 2005). Pirkenseer et al. (2010, 2011) record a total of 18 Eocene and 8 Late Cretaceous species implying Ypresian to Priabonian as well as Cenomanian, Turonian to Santonian and Campanian to Maastrichtian alpine source rocks. While the material from the underlying marine “Couches à Mélettes” and “Marnes à Cyrènes” is generally well-preserved, our material from the quartz-rich sands of the basal “Molasse alsacienne s.l.” is poorly preserved and hinders a specific determination.

adult: 16 carapaces, 1 right valve

Measurements (µm)

See plate. The preservation of the remaining material is insufficient for reliable measures.

Taxonomic remarks

Oertli (1956) discusses the similarity of the taxa *Cytherella gracilis* and *C. angusta* (both erected in Lienenklaus 1894) and merges both to the former species. Uffenorde (1981) elaborates on the considerable size and shape variation of *Cytherella gracilis*. Considering the wide geographical and temporal distribution (see below) of this species a revision of small, elongated rectangular, sparsely ornamented or smooth *Cytherella* species should be envisaged. This is illustrated by the attribution of early Eocene material from northern Spain to *Cytherella gracilis* (Ducasse 1972), which may rather conform to the regionally occurring similar *C. gamardensis* Deltel, 1964 (sensu Ducasse 1981) or Palaeocene *C. lagenalis* Marliere, 1958. This especially applies to slightly abraded material, where fine surface ornamentation may be obscured.

Type locality and horizon

Doberg near Bünde (Nordrhein-Westfalen, northwestern Germany), "Ober-Oligocän" (sensu Lienenklaus 1894), "Chattien" (sensu Oertli 1956).

Lectotype

Right valve (collection Lienenklaus), Institute of Geology, University of Göttingen (Germany).

- 2008 *Cytherella gracilis* – Picot et al., pl. 2, fig. 1

Geographic and stratigraphic distribution

The first record dates to the middle Eocene of eastern Germany (Pietrzeniuk 1969). Rupelian occurrences have been reported for northwestern Switzerland, eastern France and southwestern Germany (Lienenklaus in Kissling 1896; Oertli 1956; Picot 2002; Picot et al. 2008), the Alsace (Stchepinsky 1963) and the Mainz Basin (Kammerer 1993; Grimm et al. 2005). The species has also been reported from the Chattian to Aquitanian of southern Slovakia (Brestenská 1975), the Chattian of the type locality (Lienenklaus 1894) and northern Hessen (central Germany; Faupel 1975) and the Burdigalian of the Aquitaine Basin (Moyes 1965) as well as northern Germany (Bassiouni 1962). Not illustrated reports include a continuous Chattian to Burdigalian occurrence in northern Niedersachsen (northern Germany; Uffenorde 1980, 1986), a Rupelian to Serravallian occurrence in southern Bavaria (Witt 1967), the Chattian of the northwestern Caucasus (Schweyer 1938) and ?Chattian to lower Miocene of the southern Ukraine (Scheremeta 1969).

Taxonomic remarks

Cytherelloidea jonesiana is very similar to *Cytherelloidea praesulcata* Lienenklaus, 1894 from the Oligocene of northwestern Germany. It differs by the presence of an anterior admarginal groove, and a liplike swelling of the anterior margin in dorsal view. These characteristics have also been described for material from the Chattian of the Mainz Basin (Kammerer 1993), but has not been detected further to the south in the Upper Rhine Graben. Keen (1972b) erects the subspecies *C. j. crassata* based on a freak development of the marginal ridge and attributes this either to stratigraphical reasons (in younger specimens less developed), or changing palaeoecological attributes influencing shell calcification ratios. Since we observe a range of developments of the marginal ridges in our material we rather concur with the ecological interpretation.

Type locality and horizon

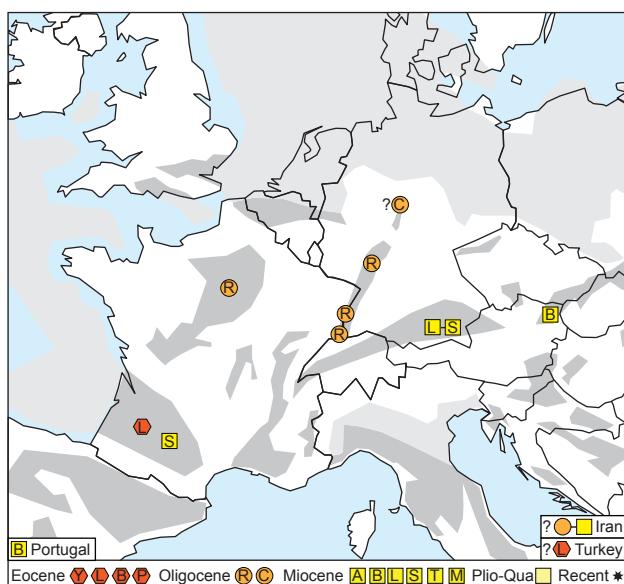

Not given, region of Jeurre or Etréchy (near Étampes, Paris Basin, northern France), "éocène supérieur", "sables de Fontainebleau" (sensu Bosquet 1852), "Stampien" (sensu Keij 1957).

Lectotype

Right valve (collection Bosquet No. 4, Keij 1957), Institut Royal des Sciences naturelles de Belgique, Bruxelles (Belgium)

Geographic and stratigraphic distribution

Lutetian of the Aquitanian Basin (SW France: Ducasse et al. 1985) and probably Turkey (Nazík 1993). Rupelian occurrences include the Basel area and the Swiss Jura (Switzerland: Oertli 1956; Keen 1972b; Picot et al. 2008), the Alsace (eastern France: Stchepinsky 1963), the Mainz Basin (Doebl & Sonne 1975), the Paris Basin (France: Bosquet 1852; Keij 1957; Keen 1972b; Ducasse et al. 1985). Material from the Chattian of northern Hessen (central Germany; Faupel 1975) may possibly be attributed to the species. Younger, not illustrated reports date to the Burdigalian of Portugal (Pais et al. 2012) and Austria (Rögl et al. 1997), the Serravallian of the Aquitanian Basin (Ducasse & Cahuzac 1997) and the middle Miocene of southern Bavaria (Witt 1967).

Taxonomic remarks

Note the difference in the size ranges between varying samples (see measures of SEM images and text-fig. 26 in Pirkenseer & Berger 2011). Large variations in outline shape hampers an entirely unambiguous separation of female and male specimens. The measuring of carapaces revealed the variability between left and right valves in individual specimens and between specimens.

The probably endemic late Rupelian *Cytheridea sandbergeri* is closely related to the coeval *Cytheridea pernota* from northwestern Europe. Formerly the latter species has been described from sediments of the Upper Rhine Graben and the northern Jura (Oertli & Key 1955; Picot et al. 2008).

The presence of *Cytheridea sandbergeri* in early Rupelian sediments of the Upper Rhine Graben sensu Griebemer et al. (2007) has been emended (Pirkenseer & Berger 2011). The occurrence of *Cytheridea sandbergeri* as far east as the Tarim Basin and as early as the late Eocene (Bosboom et al. 2014) seems doubtful.

Taxonomic remarks

Cyamocytheridea punctatella sensu Oertli (1956) is a morphologically variable species. Less well rounded, more semicircular specimens are interpreted to represent males, whereas the more ovoid individuals are attributed to females. Accordingly different morphs have been either reassigned to a new species (*Cyamocytheridea* sp. A in Kammerer 1993, *C. cf. devexa* and *C. cf. hebertiana* in Pirkenseer & Berger 2011) or subspecies (*C. p. producta* in Margerie 1961; Keen 1972b, 1978). The development of tubercles is restricted to juveniles by Oertli (1956). In part of our material and Pirkenseer & Berger (2011) also adult-sized specimens carry vesicles.

Both *Cyamocytheridea hebertiana* (Bosquet 1852) from the Eocene of the Paris Basin and *C. devexa* (Lienenklaus 1905) from the Rupelian of the Mainz Basin are larger and feature lower and narrower posterior and anterior valve margins.

Type locality and horizon

Jeurre and Étréchy near Paris (France), Bergh near Kleine-Spouwen (Belgium), "argile sableuse à *Nucules*", exact locality and horizon not given.

Holotype

Not given, material lost according to Kammerer (1993).

Geographic and stratigraphic distribution

Cyamocytheridea punctatella occurs in the southern part of the northwest European Cenozoic Basin (northern France, southern England and Belgium) in the Rupelian (Keen 1972b, 1978, 1989) and also the Chattian of the Paris Basin (Ducasse et al. 1985a). The species is recorded from the early Oligocene to the Serravallian in the Aquitaine Basin (southern France: Moyes 1965; Ducasse et al. 1985; Ducasse & Bekaert 1996) and the early Miocene of the Montpelier Basin (southern France: Carbonnel 1970). The species is present in the Rupelian of the entire Upper Rhine Graben (Oertli 1956; Malz 1962; Stchepinsky 1963; Picot 2002; Picot et al. 2008). The species occurs in the early Miocene (Carbonnel 1982) of the western Molasse Basin, in the Chattian and Langhian of southern Bavaria (Witt 1967; Müller 1985) as well as the Chattian to Aquitanian of the southern Slovakia and northern Hungary (Brestenská 1975), and possibly the entire Oligocene of northern Hungary (Monostori 2004).

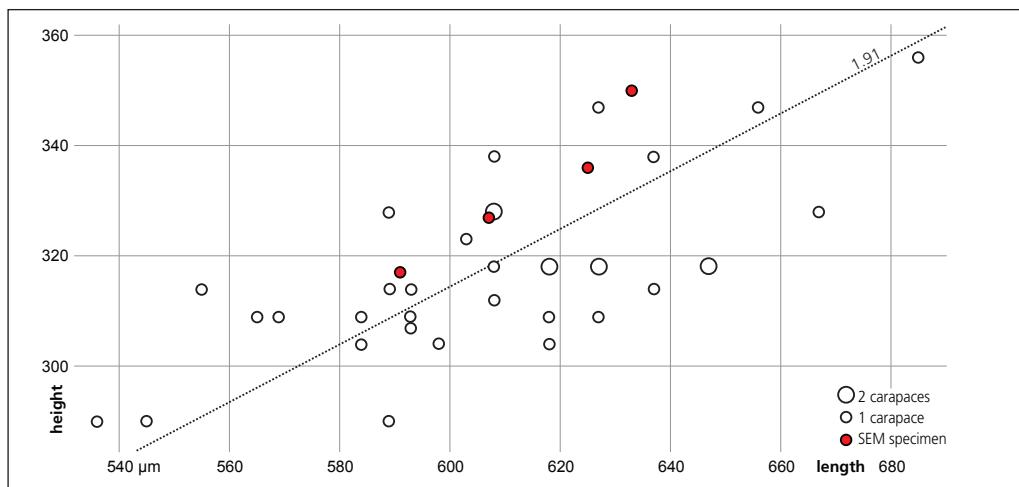

Fig. 8. Length/height plot of *Cyamocytheridea punctatella* carapaces (sample BEE004-306). The wide diffuse scatter compares to the scatter illustrated in Pirkenseer & Berger (2011), but in our case may be partly due to the rather poor preservation.

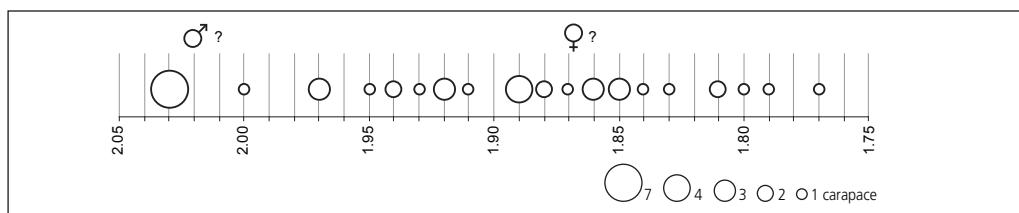

Fig. 9. Distribution of length/height ratios of *Cyamocytheridea punctatella* carapaces (sample BEE004-306). No distinctive clustering is evident.

Taxonomic remarks

Note the difference in the size ranges between varying samples (table 1 & 2, fig. 10-13), with the specimens from the Delémont Basin (HRT988-28) being larger on average than those from the Ajoie (ETA004-129). Similar size differences between two localities (smaller in drilling DP-202 to the north, larger in drilling Allschwil-2 to the east) have been recorded from the southern Upper Rhine Graben (Pirkenseer & Berger 2011).

Noding or absence thereof is recorded in all intermediate and terminal stages. Noding starts with slight disturbance of the valve surface and irregularity in the distribution of the ornamental pits. First to appear are the two large vertically arranged nodes just behind valve-mid-length and a thickened anterior ridge. A small posteroventral node represents the third appearing element, and the final noding stage includes two small additional anteroventral and one posterodorsal nodes. In their final stage nodes themselves are accentuated by small swellings of the node surface. The merging of the species *Hemicyprideis basiliensis* (Oertli & Key 1956) and *H. helvetica* as (noded, smooth or intermediate) ecomorphotypes of *H. helvetica* has been outlined in Pirkenseer & Berger (2010).

Type locality and horizon

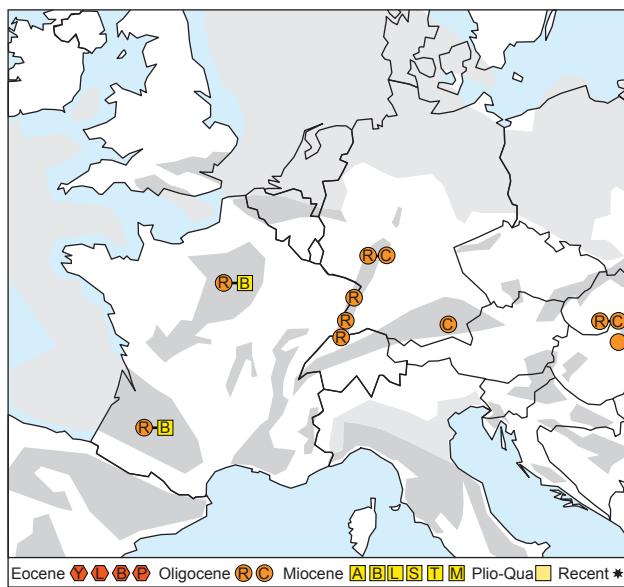

Mine shaft Lachat, La Communance, southwest of Delémont (sample 161) (NW Switzerland), "Blaue Tone", Rupelian (sensu Oertli 1956)

Lectotype

Female right valve (chosen by Oertli 1956), collection Lienenklaus, Geological Institute University of Göttingen (Germany)

Geographic and stratigraphic distribution

Hemicyprideis helvetica occurs in the Rupelian to Burdigalian in the Aquitaine and Paris Basin (Ducasse et al. 1985; Ducasse & Bekaert 1996), the Rupelian of the Upper Rhine Graben (Lienenklaus 1895; Oertli 1956; Stchepinsky 1963; Malz & Triebel 1970; Kammerer 1993; Picot 2002; Picot 2008; Pirkenseer & Berger 2011), early Chattian in the Bavarian Molasse Basin (Müller 1985) and the Oligocene of Hungary and Slovakia (Brestenská 1975; Monostori 2004). The Miocene records are probably due to incorrectly identified material.

diverse samples	Stade	Quantity	Length	mean	Height	mean	le/he	mean
	A-1 stage L	1	582	–	374	–	1.55	–
	A-1 stage R	1	579	–	349	–	1.66	–

Taxonomic remarks

A detailed overview of the species is given in Malz (1973). The coeval *Neocyprideis williamsoniana* (Bosquet 1852) differs in its larger size, the more densely pitted valve surface, a more inflated posterior end, a lower L/H-ratio and a more concave ventral margin. The very similar *Neocyprideis enkheimensis* Malz, 1973 from the early Miocene of the northern Upper Rhine Graben differs only in its steeper posterodorsal part of the posterior margin and the somewhat greater width. *Neocyprideis aquitanica* Kollmann & Moyes, 1963 from the early Miocene of the Aquitaine Basin differs in a lower L/H-ratio and a non-vertical posterior margin (e.g. Bassiouni 1979).

	male R	2	648-675	662	358-370	364	1.81-1.82	1.82

Taxonomic remarks

Schuleridea rauracica differs from *S. perforata* in a less pointed dorsal and caudal angle and hence a more rounded, less triangular lateral shape (Oertli 1956). The three size outliers correspond to the size differences between the localities Sorne and Birse River Bed mentioned in Oertli (1956). Historically much material from the Eocene to the Miocene was attributed to the *Schuleridea perforata* group (including specimens adhering to *S. rauracica*), the unlikeliness of which has been commented on by e.g. Oertli (1956), Kollmann (1958) and Moos (1970).

Type locality and horizon

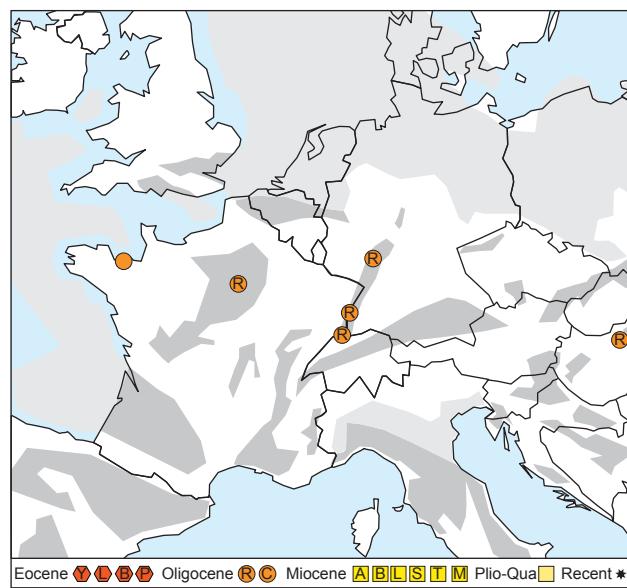

locality 167, River Sorne bed southwest of Delémont (NW Switzerland), "Blaue Tone", "Rupelian" (sensu Oertli 1956).

Holotype

Male right valve, MOOE330/1, Naturhistorisches Museum Bern (Switzerland).

Geographic and stratigraphic distribution

Schuleridea rauracica occurs in the late Rupelian of the Delémont Basin (Oertli 1956; Picot et al. 2008), the Alsace (Stchepinsky 1963), the Mainz Basin (Doebl & Sonne 1975) and potentially the Ajoie subbasin (Picot 2002), the Rupelian of Hungary (Monostori 2004) and the Paris Basin (Kollmann 1958; Ducasse et al. 1985) as well as the Oligocene of the Bretagne (Apostolescu 1963).

		1	875	–	343	–	2.55	–

Taxonomic remarks

The resembling Priabonian *Pontocythere haskinsi* (Keen 1977) from the Hampshire Basin is distinctly smaller than *P. therwilensis*, with the highest point in lateral view lying much closer to the posterior end of the valve of the latter species. *Pontocythere lithodomoides* (Bosquet 1852) from the Rupelian of the Paris Basin and Belgium is of a comparable size to *P. therwilensis*, but differs in extending the lateral concentric ridges to the ventral part of the valve and a more arched dorsal margin (following the emendation in Keij 1957).

Synonymy

male R	4	820-840	829	454-473	461	1.78-1.81	1.80

Taxonomic remarks

Both subspecies of *Hammatocythere hebertiana* may in fact represent a single pool of morphotypes, since published images and our material show transitional ornamentation (e.g. specimen figured in Lord et al. 2009). Polymorphism within the subspecies *trituberculata* has already been highlighted in Ducasse & Rouselle (1979). This concerns the number (2-4) and degree of formation (continuous, intermittent, traces) of the ridges anterior to the subcentral tubercle, the strength of the reticulation and position of individual reinforced ridges as well as the prominence of the clear area behind the anterior marginal rim (e.g. Keen 1972b). Extensive polymorphism has also been discussed for the sister taxon *Hammatocythere oertlii* (Ducasse & Rouselle 1978).

Despite the generally weak development of the reticulation most sola can be assigned to the main lateral fossal patterns sensu Liebau (1969) and Benson (1972) (fig. 3). Identification of pore cones is much more difficult due to the low stature or absence of cones as well as their integration as a part of the thickened lateral ridges. The position of the latter may not be consistent. The position of the postero-median ridge of specimen pl. 55.1, 3 lies between fossae rows M and N, whereas in specimen pl. 55.2 it lies one row further ventral (N and O).

Taxonomic remarks

The genus *Leguminocythereis* Howe, 1936 is based on Oligocene North American material. Liebau (1975) argues that resembling European material represents an analogous development within the Hammatocytherini, as opposed to true *Leguminocythereis* being part of the Buntoniinae.

"Leguminocythereis" lienenklausi represents a contemporaneous species in the southern Upper Rhine Graben, but is easily distinguished by a linear arrangement of lateral ornamentation and the lack of the pronounced anterior ridge and adjacent groove parallel to the second lateral mesh row. A slight overlap of female and male morphotypes exist, hindering a clear distinction of sexes in intermediate specimens (see measures and plates).

Synonymy

Genus not established (sensu Liebau 1975)

Type species: not assignable

Taxonomic remarks

Bosquet (1852) mentions three type localities distributed over northern France and Belgium. Keij (1857) merges Bosquet's material with *Pterygocythereis fimbriata* (v. Münster 1830), however figures one specimen (he considers to represent a juvenile) likely belonging to *P. ceratoptera*. Since Bosquet's illustrated specimen appears rather schematic (though bearing characteristics later attributed to *P. ceratoptera*), and not linked to any of the proposed localities it remains impossible to deduce a definite type locality. This may also have influenced the decision of Ducasse et al. (1985) to treat the French material as *P. fimbriata* (though the figured specimen clearly represents *P. ceratoptera*).

Pterygocythereis fimbriata (v. Münster 1830) represents a resembling but distinct coeval European species (Guernet 1990; Pirkenseer & Berger 2011), whereas *P. coronata* (Römer 1838) (and the synonymous *P. siveteri* Athersuch 1978) may be considered as younger successor taxon. Recent material of *P. jonesii* (Baird 1850) has often been dubbed *P. ceratoptera* (e.g. Bonaduce et al. 1975). Since all of these taxa look superficially similar, the reader is advised to consult the overview of the genus *Pterygocythereis* summarised in Guernet (1990). An exhaustive list of synonymy is provided below. Care should also be taken in case ecomorphotypes may be present, as is the case with "*P. helvetica*" and "*P. retinodosa*" (sensu Oertli 1956), which adhere however to *P. ceratoptera* (Pirkenseer & Berger 2011).

Type locality and horizon

not designated, Rupelian (sensu Bosquet 1852):

Rupelmonde (Belgium), "argile de Basele"

Bergh/Kleine-Spouwen (Belgium), "couche argilo-sableuse à Nucules"

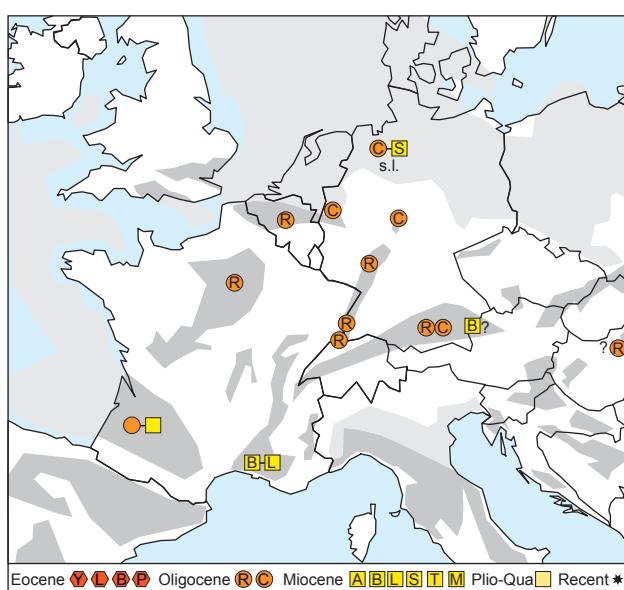

Étampes (France), "Sables de Jeurre et d'Étrechy"

Holotype

Not designated, left valve and carapace figured; "collection Bosquet", depository not given.

Geographic and stratigraphic distribution

Pterygocythereis ceratoptera is widely distributed in the Oligocene of western Europe (Aquitaine, Paris, Belgium, North-Germany and the Molasse Basin as well as the Upper Rhine Gaben). Miocene occurrences are less common and remain (partly) doubtful due to lack of taxonomic information.

Temporal and spatial distribution of *Pterygocythereis ceratoptera* in the Cenozoic of Europe.

geometric forms = epochs letters = stages
 without letters = epoch (nonspecific)

	adult L	1	944	–	522	–	1.81	–
	adult R	1	977	–	493	–	1.98	–

Taxonomic remarks

The similar-sized, potentially ancestral species *Pterygocythereis aquitanica* Ducasse, 1964 from the middle-late Eocene of the Aquitaine Basin (France) differs in a more rectangular lateral outline (less sloping dorsal margin) and in bearing a continuous dorsal ridge.

Synonymy

- 2011 *Pterygocythereis volans* – Pirkenseer & Berger, p. 70-71, pl. 10, fig. 6-7

Type locality and horizon

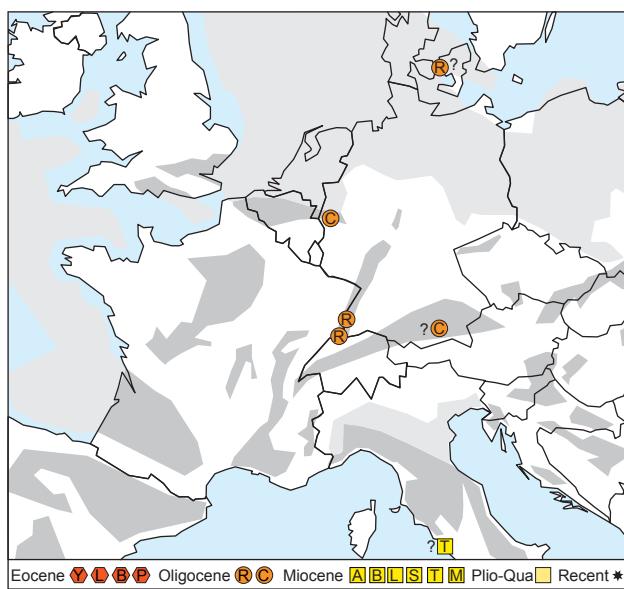

Sample 158, River Sorne bed near Delémont (Switzerland), "Blaue Tone" (Rupelian sensu Oertli 1956).

Holotype

Right valve, MOOE 460/1, Museum of Natural History, Bern (Switzerland).

Geographic and stratigraphic distribution

Occurrences are limited to the Rupelian of the southern Upper Rhine Raben and the northern Jura (Oertli 1956; Picot 2002, Pirkenseer & Berger 2011) and the Chattian of western Germany (Ziegler 1994). Uncertain occurrences include the Rupelian of Denmark (Vinken [ed.] 1988), the Chattian of Bavaria (Müller 1985) and a doubtful report from the Tortonian of Sicily (Ruggieri 1961).

Taxonomic remarks

The internal morphological characteristics of this rare species can not be observed in our material and are neither sufficiently described in the literature. Oertli (1956) gives a good overview, however remains doubtful about a definite generic classification. Hence this species can still not be unambiguously attributed to the genus *Echinocythereis* (summed up generic classification in Morkhoven 1963). The distinctive feature of posteroventral and postero-median swellings (in varying degrees) can be observed in all of our specimens. Oertli (1956) hints at the variability of the ornamentation of this species possibly being linked to palaeoenvironmental stress. Oertli (1956) considers *Echinocythereis ligula* as descendant from *E. scabra*.

Due to the dualism of tubercles (sensu classical *Echinocythereis*) and a partial development of a reticulation most sola or intratubercular spaces can be assigned to the main lateral fossil patterns sensu Liebau (1969) and Benson 1972) (fig. 3). Identification of pore cones is not possible due to the abraded nature of the material and the ubiquitous presence of ornamental tubercles.

Type locality and horizon

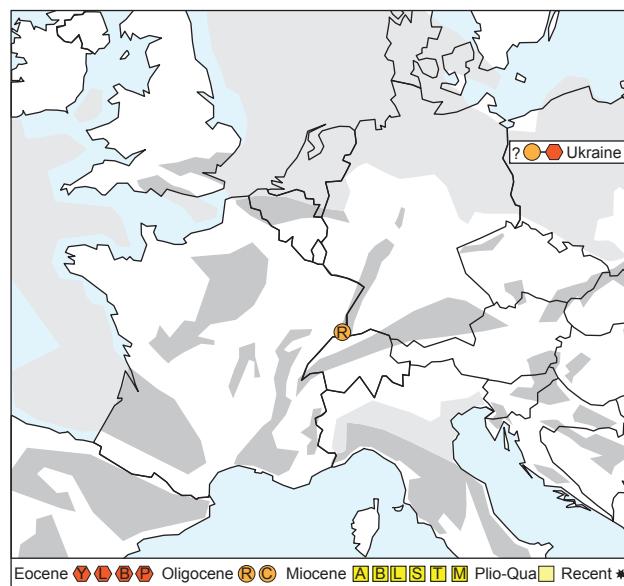

La Communance (Jura), Delémont Basin (NW Switzerland), "Mittel-Oligocän" [late Rupelian] (sensu Kissling 1896)

Holotype

Adult carapace, left and right valves as well as juvenile left valve figured, depository not given.

Geographic and stratigraphic distribution

Late Rupelian of the Delémont Basin (Lienenklaus in Kissling 1896; Oertli 1956; Picot et al. 2008), possibly the Paleogene of the Ukraine (Scheremeta 1969). The specimen figured in Monostori (2004) does not represent this species. Accordingly it potentially represents a species endemic to the Upper Rhine Graben.

	<i>P. sp.</i> C	1	579	–	380	–	1.52	–

Taxonomic remarks

The similarity of several Oligocene species of *Pokornyella* and the variation of the *P. limbata* species concept sensu different authors leads to an uncertainty regarding precise specific attribution, especially when poor preservation is taken into account. Oertli (1956) gives a concise account on material he considers to represent valid *P. limbata* specimens. His figured material shows distinctly triangular specimens (females) and comparatively lower males, with a slender outline in dorsal view. This deviates from the specimen figured in Keij (1956), which while laterally looks quite similar sports a wide outline in dorsal view (more akin to *Pokornyella calix* Oertli, 1956).

Pokornyella calix according to Oertli's (1956) figures and description features a more rectangular lateral view, reduced dorsal ridges (compared to *P. limbata*) and less distinct large anterior fossae. This characterisation is more or less born out by the detailed description of *Pokornyella limbata* and *calix* morphotypes in Ducasse & Coustillas (1981), with some possible overlap (also with some *P. aff. galeata* morphs).

Problems separating these morphotypes arise with poorly preserved material, where "low" females of one species may potentially be confused with comparatively "high" males of another species. The dorsally slender *Pokornyella limbata* sensu Sönmez-Gökçen (1964) from the Rupelian of northwestern Turkey looks similar in left valves, but the highest point of the right valve lies at 2/3 length and not at the anterior cardinal angle.

Further resembling species include the middle Eocene *Pokornyella limbata anteglabra* Monostori, 1998, *P. osnabrugensis* (Lienkenklaus 1894) (lacks dorsal ridge; Moos 1965; Oertli 1956) and the more rectangular *P. lattorfiana* (Lienkenklaus 1900) (Moos 1968; both from the early Oligocene of northwestern Germany). Some differences are based on (comparatively small) variations of the lateral ornamentation, which suggests the necessity of a revision of morphologically overlapping taxa.

The scarce material from the research area can not entirely be attributed to *Pokornyella limbata*. The in dorsal view very slender specimen on pl. 61.2 may represent an abraded female featuring a much finer lateral punctuation (ecomorphotype?).

Measurements (μm)

diverse samples	Stade female C	Quantity	Length	mean	Height	mean	le/he	mean
		1	879	–	473	–	1.86	–

Taxonomic remarks

Cytheretta bernensis is characterised by its medium size, fine punctuation distributed over the entire valve surface, delicate anastomosing ridges and a - partly strongly pronounced (in females) - posteroventral valve bulge, leading to a cuneiforme outline in dorsal view (see *Cytheretta tenuistriata*, fig. 29) with rather blunt posterior and anterior ends.

Cytheretta tenuipunctata (sensu Keen 1972a) is very similar in size and morphology except for a more lenticular outline in dorsal view and the lack of posteroventral bulges. Keen (1972a) attached *Cytheretta bernensis* to the *C. tenuipunctata* superspecies and maintains the distinction from the larger *C. tenuipunctata* (as opposed to Keij 1957; see discussion for *Cytheretta tenuistriata*).

Taxonomic remarks

In 1852 Bosquet described and figured *Cythere jurinei* v. B *tenuipunctata* from the Oligocene of Belgium featuring small indistinct punctae on the entire valve surface arranged in longitudinal rows in weakly developed grooves. He indicates a length of 950 µm for the figured specimen. Reuss' (1853) species definition of *Cytherella tenuistriata* from the Oligocene of the Mainz Basin reads similar, however mentions the arrangement of the punctae in single or double rows and the position of the greatest width in the posterior third of the valve, but does not indicate the size. His type figure suggests the presence of a partly diagonal arrangement of punctae.

A first thorough overview of the species *Cytheretta tenuistriata* was elaborated in Triebel (1952) based on new material from the type locality (see there for more details). This large-sized taxon (1080-1130 µm in females, 1220-1280 µm in males) features 6 to 8 indistinct longitudinal ridges of which the median ones merge to an elliptical spot over the adductor muscle scars and surround a double row of punctae. Ornamentation is absent in the posterior and anterior part of the valve. Triebel (1952) also erects the species *Cytheretta posticalis*, which is identical in shape but of somewhat smaller size, with the only distinguishing feature being the strongly reduced ornamentation. The latter consists of a remnant of a rhombical mesh of delicate ridges restricted to the area above the posteroventrolateral valve bulge. This mesh surrounds fields of fine punctae, with the ornamentation being more pronounced on the right valve.

Keij (1957) synonymises *Cytheretta tenuistriata* with *C. tenuipunctata*, without taking into account the size differences (his lectotype chosen from Bosquet's material measures only 960 µm) and the different provenance of both species. His description is nearly identical to Triebel's (1952), adding the potential for some anastomosing of ridges and a lack of ornamentation also on the dorsal side. Oertli (1956) puts three new species of *Cytheretta* (*bernensis*, *variabilis*, *triebeli*) from the Oligocene of northwestern Switzerland in context to *C. tenuistriata* and *C. posticalis*, however does not reference *C. tenuipunctata*.

Due to the pronounced size difference of co-occurring specimens despite the similarity in ornamentation and shape Keen (1972a) maintains both species, but attributes both taxa (including others) to the superspecies *Cytheretta tenuipunctata*. Interestingly he does not include *Cytheretta posticalis* in the superspecies, despite the similarities mentioned by Triebel (1952). *Cytheretta klähni* Stchepinsky, 1963 from the Rupelian of the Alsace is included in the synonymy since it was separated based only on an intermediate ornamentation and shape in dorsal view.

Our material includes abundant transitional specimens (shape, size and ornamentation) intermediate to *Cytheretta tenuistriata* and *C. posticalis* sensu Triebel (1952). Since both taxa originate from the same type region (Mainz Basin), which is part of the larger Upper Rhine Graben sedimentary basin, we accordingly synonymise them. Though a single small female specimen approaches a *tenuipunctata* habitus (see pl. 66.3), it is still too large to be attributed to the latter species. Accordingly we adhere to the (super)species concept sensu Keen (1972a).

Note that females and right valves of both sexes always show a higher degree of ornamentation than males and left valves. The posterior end of females in dorsal view features on average a steeper angle than males and accordingly a more cuneiform/less lenticular outline (fig. 29c). The more ornamented right valve shows a tendency to bulge out more at the posteroventrolateral part than the left valve. For otherwise similar specimens (ridge pattern, size and shape), but featuring a striking difference in punctae size compare e.g. pl. 66.1-2.

Type locality and horizon

Weinheim bei Alzey (Germany), "unterer Meeressand" sensu Reuss (1853), Rupelian sensu Triebel (1952).

Holotype

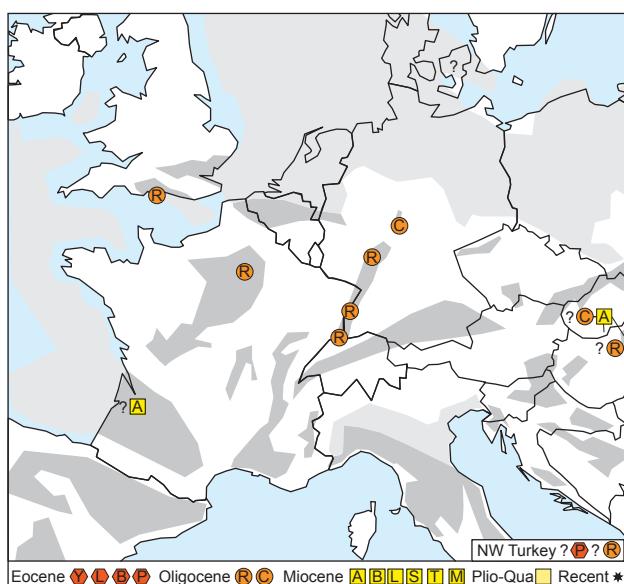

Not designated, material lost (see Triebel 1952).

Neotype

Male carapace chosen from new material from the type locality (Triebel 1952), X/e 1635, Senckenberg Museum, Frankfurt a.M. (Germany).

Geographic and stratigraphic distribution

Cytheretta tenuistriata occurs mainly in the Rupelian of the Upper Rhine Graben (Oertli 1956; Stchepinsky 1963; Kammerer 1993; Picot et al. 2008; Pirkenseer & Berger 2011), the Hampshire Basin (Keen 1978; Lord et al. 2009), the Paris Basin (Keen 1982) as well as in the Chattian of central Germany (Faupel 1975). Potential records include the Priabonian and Rupelian of northwestern Turkey (Sönmez-Gökçen 1973, Şafak et al. 1999), the Rupelian of Hungary and southern Slovakia (Brestenská 1975; Monostori 2004) and the Aquitanian of southwestern France (Carbone et al. 2012). The species may have occurred in a wider area, depending on a future taxonomic reevaluation of related taxa.

Temporal and spatial distribution of *Cytheretta tenuistriata* in the Cenozoic of Europe.

geometric forms = epochs letters = stages

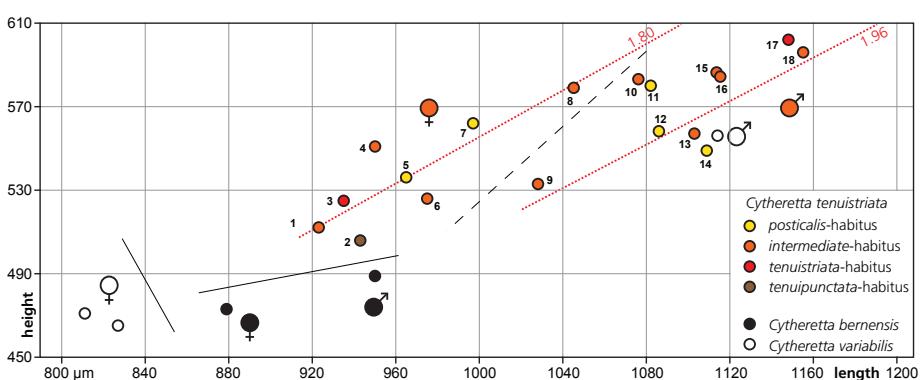

Fig. 27. Length/height plot of colour-coded *Cytheretta* spp. carapaces.
Small numbers in bold denote equivalent carapaces in fig. 27 and 28. Close position of large females (8) and small high males (10, 11) may lead to misinterpretation in isolated specimens. Note the much larger *Cytheretta variabilis* male.

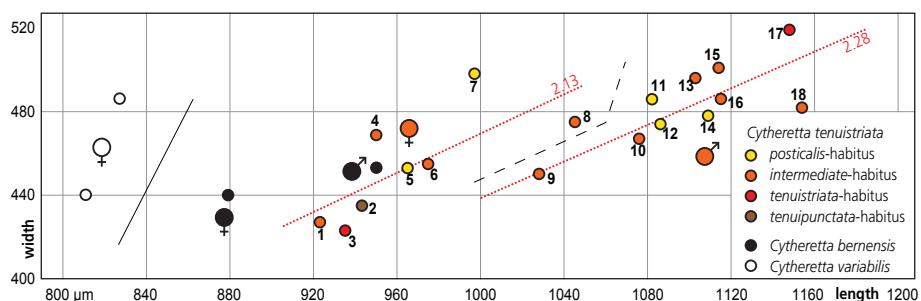

Fig. 28. Length/width plot of colour-coded *Cytheretta* spp. carapaces.
Note the more consistent clustering of intermediate males (10, 11) from fig. 27. Female 8 shows conform L/H-ratio in fig. 28, but "male" L/W-ratio in fig. 28.

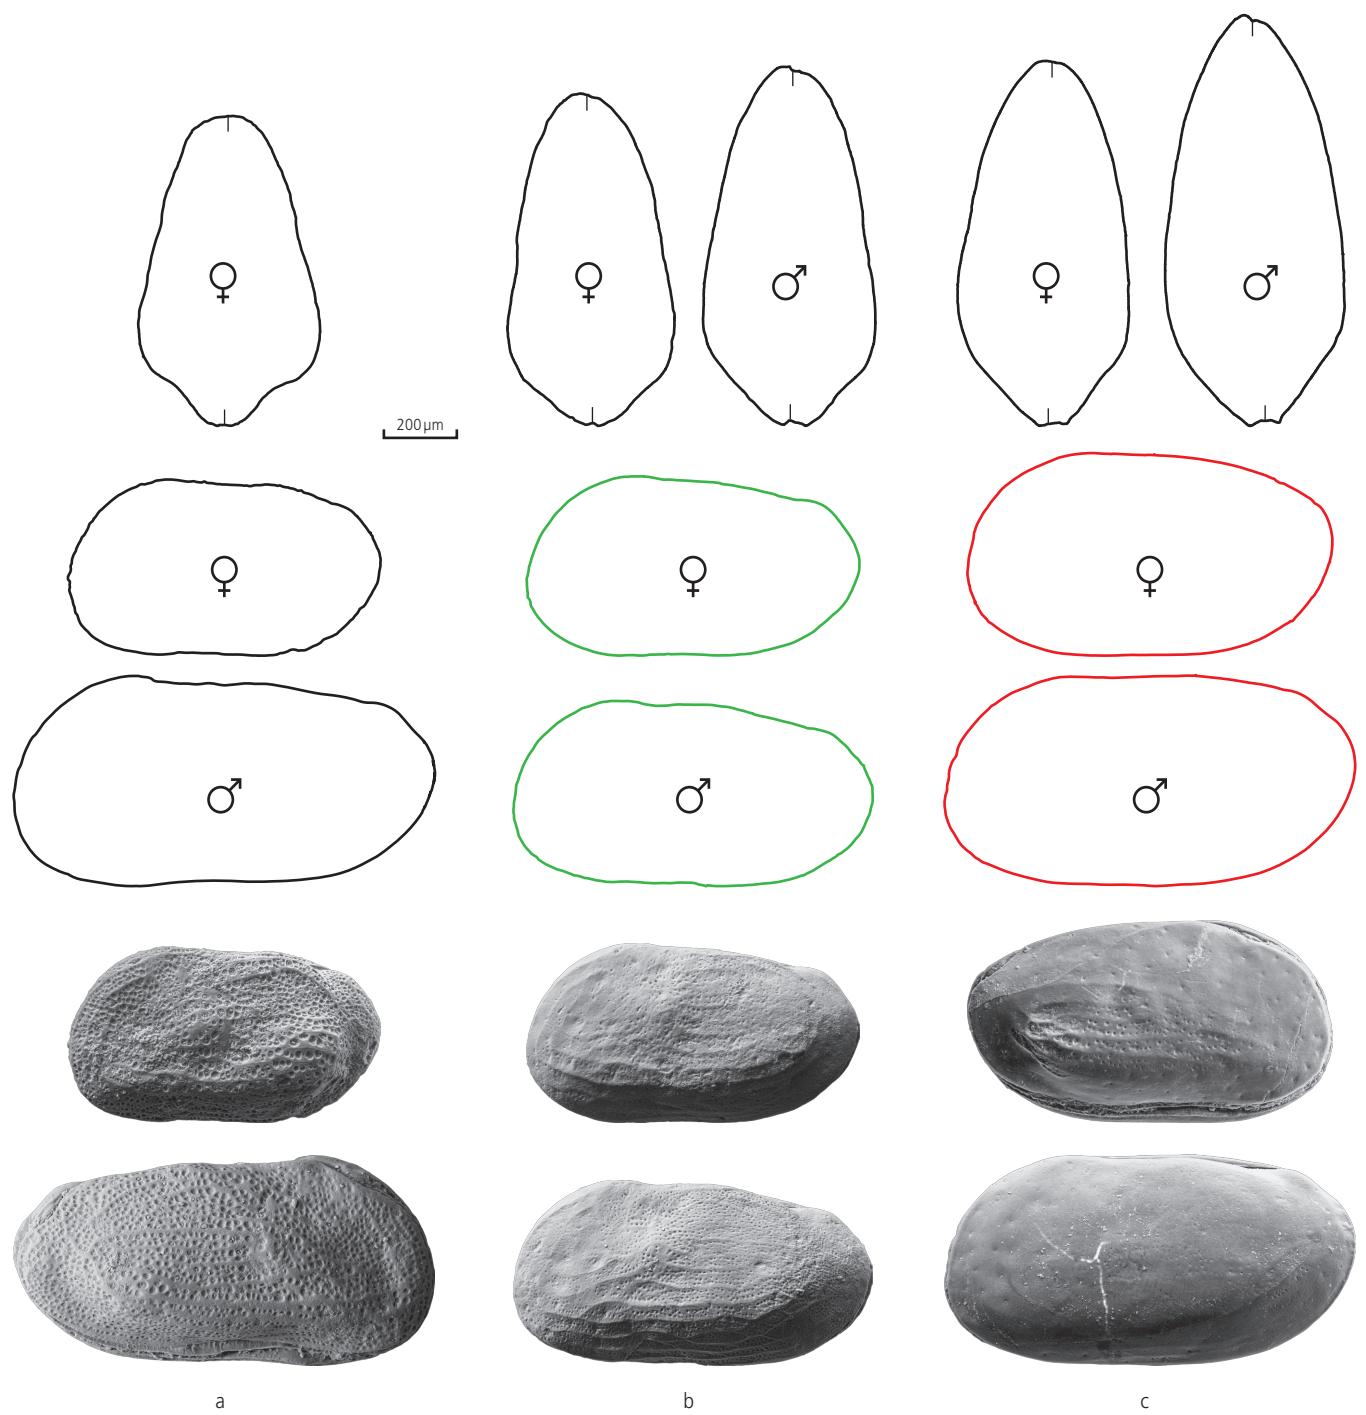

Fig. 29. Ornamentation and dorsal view vs. lateral view outline comparison of *Cytheretta* carapaces from the research area.

a) *Cytheretta variabilis*: note the pronounced lateral bulge near the posterior end, the coarse punctation, the widely rounded anterior end, the slightly concave ventral margin and the slightly "humpbacked" dorsal margin. Note the exceptionally large male specimen.

b) *Cytheretta bernensis*: intermediate features including less pronounced posterior lateral bulges leading to a more cuneiform dorsal view. Ornamentation consists of fine punctation on the entire valve surface and fine anastomosing ridges.

c) *Cytheretta tenuistriata* standard specimens (no 5 & 12 from fig. 27 & 28): reduced ornamentation, ovoid lateral outline and more lenticular outline in dorsal view.

Taxonomic remarks

Cytheretta variabilis is characterised by its medium size, a coarse punctuation distributed over the entire valve surface, very broadly rounded anterior margin in lateral view and a pronounced posteroventral valve bulge, leading to a distinct outline in dorsal view (see *Cytheretta tenuistriata*, fig. 29) with blunt anterior margin and strongly concave outline between the posterior end and the greatest width. Keen (1972a) tentatively attached *Cytheretta variabilis* to the *C. tenuipunctata* superspecies, which appears to be justified when comparing the ridge patterns in both taxa.

Poorly preserved material from the Rupelian of Hungary has been attributed to *Cytheretta variabilis*, which otherwise seems to represent a species endemic to the southern Upper Rhine Graben. Note that the figured specimens correspond to the extremes in size variations given in Oertli (1956).

Synonymy

Taxonomic remarks

Oertli (1956) erected the separate species *Cytheretta gutzwilieri* for material from the southernmost Upper Rhine Graben, based on a much finer reticulation and less well-developed longitudinal lateral ridges than was described for *Flexus concinnus* sensu Triebel (1952). Kammerer (1993) and Pirkenseer & Berger (2011) however merged both species due to the occurrence of intermediately ornamented specimens (showing a similar second order reticulation) interpreted to represent ecomorphotypes.

Interestingly the material in Oertli (1956) and from DEL-BEE is smaller or at the lowest end of the size spectrum cited in Kammerer (1993), Triebel (1952) and Pirkenseer & Berger (2011). Length/height-ratios in the DEL-BEE material are also considerably lower (mean female L/H 1.80 vs. 1.96) than those from the southern Upper Rhine Graben (Pirkenseer & Berger 2011).

Type locality and horizon

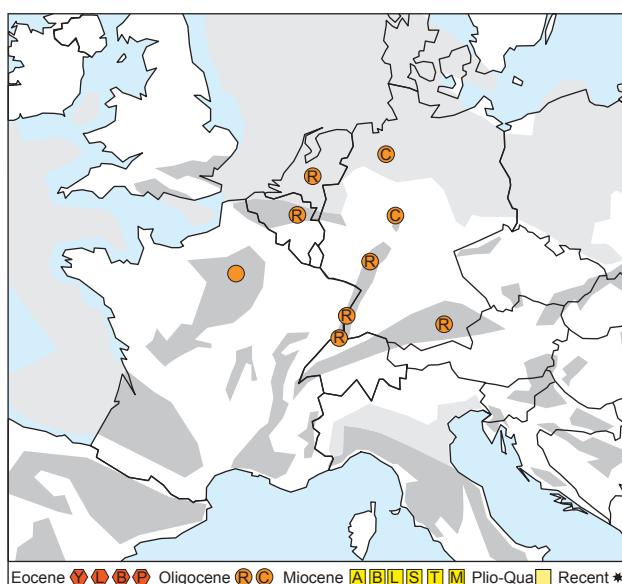

Locality Welschberg near Waldböckelheim (W Germany), "Meeressand", "Rupelian" (sensu Triebel 1952).

Holotype

Female carapace, SMF X/e 1676, Senckenberg Museum, Frankfurt a.M. (Germany).

Geographic and stratigraphic distribution (sensu authors)

Flexus concinnus is a species occurring in the Oligocene (especially the Rupelian) of central and northwestern Europe (Triebel 1952; Oertli 1956; Keij 1957; Witt 1967; Keen 1972a; Faupel 1975; Kammerer 1993; Picot et al. 2008; Pirkenseer & Berger 2011). Older (Bartonian-Priabonian; e.g. Keij 1957; Scheremeta 1971; Sönmez-Gökçen 1973) and younger (Eggenburgian: Kollmann 1971) records should be treated cautiously, since sufficient information or good illustrations are lacking.

Temporal and spatial distribution of *Flexus concinnus* in the Cenozoic of Europe.

Type locality and horizon

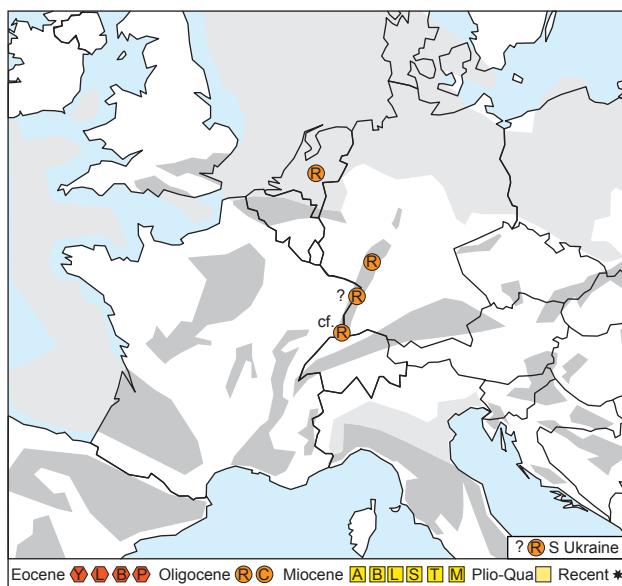

Drilling 27 (KB2), sample 6015/5921, depth 83.25-83.50 m, Bodenheim near Mainz (Germany), "mittlere Zwischenschichten, Schleichsand", Rupelian (?) (sensu Kammerer 1993).

Holotype

Female left valve, SMF Xe 15282, Senckenberg Research Institute, Frankfurt a.M. (Germany).

Geographic and stratigraphic distribution

Loxoconcha marionae occurs in the Rupelian of the Mainz Basin (Kammerer 1993) and possibly the late Rupelian of the middle and southern Upper Rhine Graben (partim? Oertli 1956; Stchepinsky 1963; Picot 2002). Other European material may also be attributed to this species, but this is hampered by a generally poor documentation (e.g. Scheremeta 1969).

Taxonomic remarks

Similar sized Oligocene *Loxoconcha* are difficult to separate due to the presence of ecomorphotypes with varying sizes and ornamentation (Keen 1982; Kammerer 1993; Pirkenseer & Berger 2011), particularly when preservation is poor. In the past this led to the description of the similar species *Loxoconcha nystiana* (Bosquet 1852), *L. tenuimargo* (Reuss 1856), *L. intorta* (Lienenklaus 1905), *L. favata* (Kuiper 1918), *L. kuiperi* (Keij 1957), *L. alsatica* (Stchepinsky 1963) and *L. marionae* (Kammerer 1993). While some species retain their status, *Loxoconcha favata*, *L. kuiperi* and *L. alsatica* must be discussed in relation to *L. nystiana* and *L. marionae*.

Already the type description and figure of *Cythere nystiana* in Bosquet (1852) presents issues, since they rather seem to allude to a species of the Trachyleberididae than the Loxoconchidae. Keij (1957) in his revision of Bosquet's material mentions a mixup of "*Echinocythereis hispida*" (original specimens from France, probably the one figured as type) with several species of *Loxoconcha*. Keij (1957) chose a right female valve from Belgium as lectotype for *Loxoconcha nystiana*, ignoring the fact that the description of Bosquet's *Cythere nystiana* rather fits a Trachyleberididae, which would have had precedence over *Cythere hispida* Speyer, 1863 (see ibid. p. 23-24, pl. 2, fig. 9).

Kuiper (1918) mentions *Cythere nystiana* in the introduction, but does not discuss this species in context with his new taxon *Loxoconcha favata*, which conforms to Keij's (1957) description. Keij's (1957) emended description, figures and measurement define a distinct species concept for *Loxoconcha nystiana*, with one feature being the marginal concentric rows of fossae. He does however not mention *Loxoconcha favata*, which possibly has precedence over *L. nystiana* if *C. nystiana* is applied to Bosquet's rather trachyleberid type description and figure. Since the type information on *Loxoconcha favata* is also ambiguous, we adhere for the time being to the *L. nystiana* concept sensu Keij (1957).

We conclude that the species features of *Loxoconcha nystiana* include a concentric pattern of fossae arrangement near the anterior, ventral and posterior valve margins. Fossae are of small to medium size and moderate depression taking on a more rounded aspect where they are more weakly developed. Fossae may be very weakly developed or absent in certain specimens / "populations", which has been referred to palaeoenvironmentally stressful habitats (Keen 1982, Kammerer 1993, Pirkenseer & Berger 2011). The posterior part of the dorsal margin is either visible or only slightly obscured in lateral view.

Part of the material from the research area is markedly different and has accordingly been related to *Loxoconcha marionae* Kammerer, 1993. Though of similar size, the fossae are more pronounced (greater height of the muri) and not arranged concentrically but partly longitudinally. The caudal process is broader both at its posterior end and posteroventral part. Together with a stronger inflation of the posterodorsal valve surface that always hides this part of the valve margin this leads to an "upturned" posterior valve portion (especially in males). Since our material does not entirely conform to these features (probably due to the inferior quality of the material), it is referred to as *Loxoconcha cf. marionae* (see ibid.). Several specimens illustrated in the literature showing a pronounced reticulation lacking a concentric arrangement may possibly belong to this species, notably in Kuiper (1918), Oertli (1956), Stchepinsky (1963) and Picot (2002).

In relation to the uncertainty regarding these species a reevaluation of the similar more or less contemporaneous Rupelian to early Miocene species of *Loxoconcha* should be considered.

Type locality and horizon

not designated, Rupelian (sensu Bosquet 1852): Bergh/Kleine-Spouwen (Belgium), "couche argilo-sableuse à Nucules" sensu Bosquet (1852), "*Nucula compta*-clay" selected as type locality by Keij (1957).
 [Jeurre and Étrechy (France), "Couche à *Ostrea cyathula*", representing "*Echinocythereis hispida*" according to Keij (1957).]

Holotype

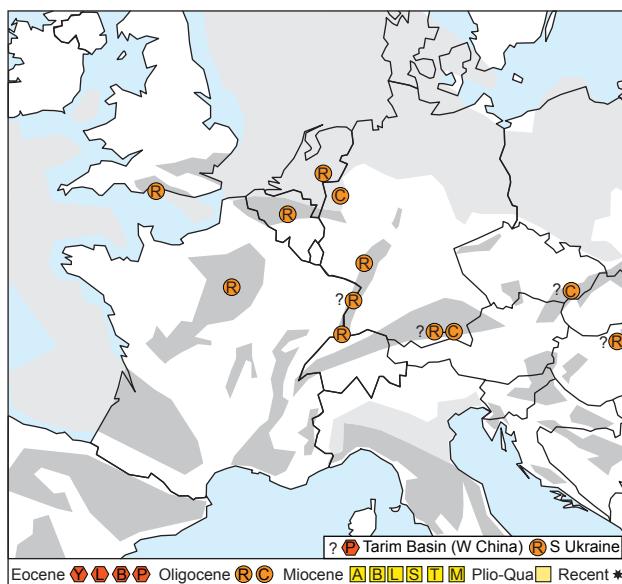

Not designated, left valve and carapace figured; "collection Bosquet", depository not given.

Lectotype

Female right valve chosen by Keij (1957), collection Bosquet No. 31, Institut Royal des Sciences Naturelles de Belgique, Brussels.

Geographic and stratigraphic distribution

Loxoconcha nystiana occurs mainly in the Rupelian of the Upper Rhine Graben (Oertli 1956; Kammerer 1993; Picot et al. 2008; Pirkenseer & Berger 2011), the Hampshire Basin (Lord et al. 2009), the Paris Basin (Keen 1982) Holland (Kuiper 1918) and Belgium (Keij 1957) as well as in the Chattian of northwestern Germany (Goerlich 1958). Potential records include the Priabonian of the Tarim Basin (Bosboom et al. 2013), the Rupelian Bavaria (Witt 1967), Hungary (Monostori 2004) and the Ukraine (Scheremeta 1969) as well as the Chattian of eastern Molasse Basin (Witt 1967) and southern Slovakia (Brestenská 1975). The species may have occurred in a wider area, depending on a future taxonomic reevaluation of related taxa.

Taxonomic remarks

For a more extensive outline of this species taxonomic relationships see Pirkenseer & Berger (2011). According to a variety of authors this species shows a wide range of shapes and ornamentation (e.g. Keij 1957; Scherer 1964; Uffenorde 1981). This prompted Kammerer (1993) to a unification of *Loxoconcha delémontensis* with *L. subovata*, with many intermediate forms between a "subrectangular" and "ovoid" morphotype. Together with a varying grade of reticulation this is considered to represent fluctuating palaeoenvironmental proxies.

Scherer (1964) and Pirkenseer & Berger (2011) consider a ventrolateral swelling of the carapace bearing low ridges that hide the median part of the ventral valve margin in lateral view as characteristic for this species. This circumstance has been figured as early as in Kissling (1896), but not commented on in most other publications. This feature is however not present in otherwise similar, strongly reticulated juvenile specimens (A-3 instars) of *Loxoconcha nystiana*. Our material is rather rectangular in lateral outline with comparatively weakly developed ventrolateral ridges.

In the past many small-sized "ovoid" and "subrectangular" Loxoconchidae have been labelled as *Loxoconcha subovata* (see synonymy list). Due to the ostensibly widespread temporal (early Eocene to late Miocene) and geographical (entire Europe, probably to Middle East) distribution and the taxonomic uncertainty we attribute a group status to this species. A thorough restudy of (Palaeogene) small-sized Loxoconchidae is advised.

Loxoconcha linearis linearis Carbonnel, 1969 from the Miocene of the Rhone Basin represents a very similar, though larger descendant species. For an overview of similar small-sized early Eocene *Loxoconcha* see Haskins (1970).

Type locality and horizon

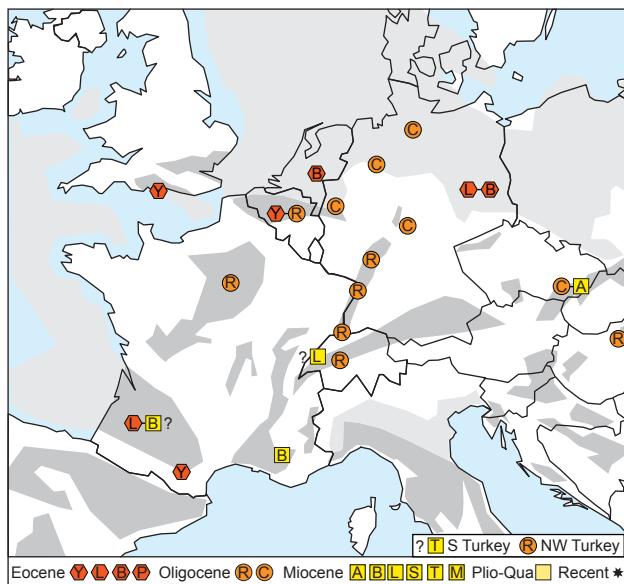

Astrup near Osnabrück (Germany), "Chattian" (sensu Kammerer 1993)

Syntypes

Left valve and a carapace, collection "v. Münster (1830)", Roemer-Pelizaeus Museum of Hildesheim (Germany) (see Malz 1987)

Geographic and stratigraphic distribution

Loxoconcha gr. subovata records are distributed over Europe. Since the type material was derived from Chattian sediments in northwestern Germany, Miocene and Eocene occurrences should be treated cautiously. Only well-documented references are figured below. Eocene records include the Aquitaine Basin (Ducasse et al. 1985, Pirkenseer et al. 2013), the Hampshire Basin (Haskins 1970; King 1991), Belgium and Holland (Keij 1957) and eastern Germany (Pietrzeniuk 1969). The Upper Rhine Graben and Mainz Basin (Oertli 1956; Doebl & Sonne 1975; Kammerer 1993; Pirkenseer & Berger 2011, Lavoyer 2013), the Paris Basin (Keen 1972b), the Swiss Molasse Basin (Scherer 1964), the Aquitaine Basin (Ducasse et al. 1985, 1991, Ducasse & Bekaert 1996), Belgium (Keij 1957), Hungary (Monostori 2004) and northwestern Turkey (Sönmez-Gökçen 1973) feature Rupelian records. Chattian occurrences are limited to middle, northern and northwestern Germany (von Muenster 1830, Lienenklaus 1894, Faupel 1975, Uffenorde 1981, Ziegler 1997) as well as southern Slovakia (Brestenská 1975). *Loxoconcha gr. subovata* has been determined in Miocene sediments of the Aquitaine Basin (Ducasse et al. 1991, Ducasse & Bekaert 1996), the southern Rhone Basin (Carbonnel 1969), the Cenozoic of the Swiss Jura (Havran 2011) and southern Turkey (Öğrünç & Nazık 1999), though most of the records remain uncertain.

Temporal and spatial distribution of *Loxoconcha gr. subovata* in the Cenozoic of Europe.

Taxonomic remarks

In relation to nomenclature the type species *Cytheropteron macroporum* Lienenklaus, 1894 should no be confused with *Cytherura macropora* from the same reference, which has been reassigned to *Microcytherura (Tetricytherura) macropora* in Moos (1971).

Eucytherura macropora seems to represent a species of relatively high morphological variability (e.g. Pietrzeniuk 1969; Moos 1973), probably related to its long temporal range (late Eocene to middle Miocene). Accordingly the very similar *Eucytherura keiji* Pietrzeniuk, 1969 from the late Eocene of eastern Germany may represent a morphotype of *E. macropora*, which is born out by the occasional attribution of *macropora*-like material to *E. keiji* (e.g. Faupel 1975; Barbin & Guernet 1988).

The very small (270-290 μm) and morphologically different subspecies *Eucytherura macropora pygmaea* Ohmert, 2017 should be assigned to a new species. A naming conflict arises however from the precedence of *Cypridina pygmaea* Reuss, 1850, which has been assigned to the genus *Eucytherura* in Sissingh (1972) and Oteanu (2006). To complicate matters the type length given in Reuss (1850) is very short (300 μm), whereas *Eucytherura pygmaea* sensu Sissingh (1972) from the Miocene of Greece is much larger (420 μm) and looks similar to *E. macropora* and hence underlines the necessity of a redisussion of the taxon *pygmaea*.

Type locality and horizon

Doberg near Bünde (Germany), exact locality and horizon not given, "Upper Oligocene" sensu Lienenklaus (1894).

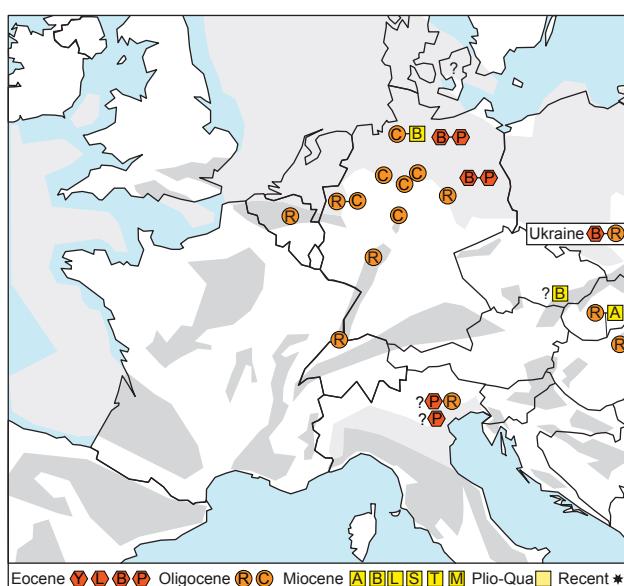

Lectotype

Left valve, chosen from type material by Kammerer (1993), IMGP Gö 361-70-1, collection Lienenklaus, Geological Institute Göttingen.

Geographic and stratigraphic distribution

Eucytherura macropora occurs in the late Eocene of eastern Germany (Piertzeniuk 1969), the late Eocene to Rupelian of Ukraine (Scheremeta 1969), the Rupelian of the Upper Rhine Graben (Lienenklaus in Kissling 1896; Doebl & Sonne 1975; Kammerer 1993), Belgium (Keij 1957), Hungary (Monostori 2004) and northeastern Germany (Moos 1973), the Rupelian to Aquitanian of southern Slovakia (Brestenská 1975), the Rupelian to Chattian of western Germany (Goerlich 1958), the Chattian of central and northwestern Germany (Lienenklaus 1894; Moos 1973; Faupel 1975; Uffenorde 1981, 1986; Mostafawi 1988) as well as the Miocene of northern Germany (Uffenorde 1981, 1986).

Potential records hail from the Priabonian to Rupelian of northeastern Italy (Ascoli 1969; Barbin & Guernet 1988) as well as the Burdigalian of the southern Czech Republic (Kheil 1967).

Taxonomic remarks

The small and schematic type figure of *Semicytherura alata* seems to overemphasise the carapace width compared to the type description, leading to a very inflated, nearly circular outline in dorsal view. The morphological variability of this species has been stressed by Moos (1971) and illustrated by Doebl & Sonne (1975) and Kammerer (1993), amongst others. The alae in our material appear blunted due to poor preservation.

Semicytherura reticulata (Lienenklaus 1894) from the same type area is very similar and may well fall within the morphological variation of *S. alata*. Due to its larger size and the accounts of Oertli (1956) and Moos (1971) the species status is kept valid. *Semicytherura hoplites* (Egger 1858) from the early Burdigalian of Ortenburg (Bavaria) looks similar (though type figure and description are very schematic), but is larger according to the author. The strongly inflated (in dorsal view) similar-sized *Semicytherura rothauseni* Schäfer, 1993 from the Chattian-Aquitaine of the Mainz Basin and smaller *S. dunkeri* Moos, 1971 from the Rupelian of central Germany lack distinct alae and feature a shorter, rounded caudal process.

The material recorded by Sönmez-Gökçen (1973) from the Rupelian of northwestern Turkey bears strong resemblance to *Semicytherura alata* in size (the given height measure seems to be exaggerated compared to the figured specimen) and shape.

Female left valve, chosen from type material by Oertli (1956), collection Lienenklaus, Geological Institute Göttingen.

Geographic and stratigraphic distribution

Semicytherura alata occurs in the Rupelian of the Upper Rhine Graben (Lienenklaus in Kissling 1896; Oertli 1956; Doebl & Sonne 1975; Kammerer 1993) and northeastern Germany (Moos 1971), the Rupelian to Aquitanian of southern Slovakia (Brestenská 1975), the Chattian of central and north-western Germany (Lienenklaus 1894; Moos 1971; Faupel 1975; Uffenorde 1986) as well as the Miocene of northern Germany (Uffenorde 1980, 1986). A potential record stems from the Rupelian of northwestern Turkey (Sönmez-Gökçen 1973).

The occurrence of the species in the Aquitanian of the Lisbon area (Nascimento 1981) and the Ypresian of northern Spain (Ducasse 1972) can not be verified due to insufficient documentation.

Taxonomic remarks

Recent *Semicytherura sella* and *S. striata* (Sars 1866) and *S. rara* (Mueller 1894) are somewhat similar in dorsal view, ornamentation and outline, but not identical. The type description in Lienenklaus (1895) conforms well to our specimen, except for the ornamentation ("large shallow fossae between longitudinal ridges"), which is also mirrored by the illustration in Keij (1957). Kammerer (1993) describes and figures new material from the Mainz Basin and elaborates on the high variability of the ornamentation. Accordingly he places the delicately ornamented *Semicytherura porcina* (Keen 1972b) in tentative synonymy. Kammerer (1993) raises the subspecies *Semicytherura gracilis foliacea* Moos, 1971 to species status. Eocene records (Scheremeta 1969; Haskins 1979) are poorly documented and thus unreliable.

Taxonomic remarks

The very elongated *Paracypris aerodynamica* resembles the widely distributed Recent *P. polita* Sars, 1866 and the early Rupelian *P. propinqua* Triebel, 1963 from the Mainz Basin (Germany). The latter species is relatively higher, features distinct cardinal angles and a more dorsally positioned posterior end, while the former appears more stocky and arcuate in lateral view (Oertli 1956).

Type locality and horizon

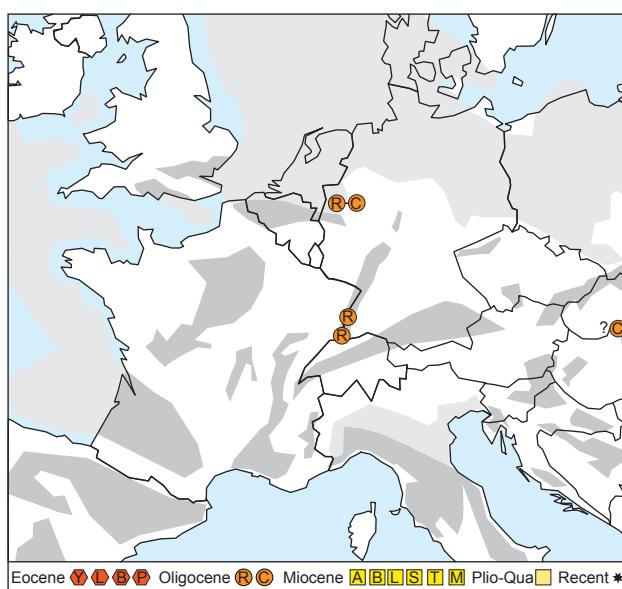

"Tongrube Laufen", clay pit near Laufen (Switzerland), "Blaue Tone", Rupelian (sensu Oertli 1956).

Holotype

Carapace, MOOE 1110/1, Natural History Museum of Bern (Switzerland).

Geographic and stratigraphic distribution

Paracypris aerodynamica shows a rather restricted occurrence in the late Rupelian of the southern Upper Rhine Graben (Oertli 1956; Stchepinsky 1963; Picot 2002) and the middle Oligocene of northwestern Germany (Goerlich 1958; Ziegler 1994). Records further to the east cannot be verified due to a lack of information (Scheremeta 1971 ; Brestenská 1975).

Taxonomic remarks

The genera *Phlyctenophora* Brady, 1880 and *Ghardaglaia* Hartmann, 1964a of the subfamily Paracypridinae (e.g. Hartmann & Puri 1974) were mainly separated by means of their soft part anatomy. Both feature branching anterior marginal pore channels (e.g. Hartmann 1974; Puri & Hulings 1976) and somewhat similar arrangement of muscle scars. The latter have not been illustrated for the type of *Phlyctenophora* in Brady (1880), and the type figure of *P. zealandica* remains vague even in the lectotype designation in Puri & Hulings (1976). Hartmann (1964b) even considers *Phlytenophora* to represent a junior synonym of *Paracypris*, however with partial validity restored in Hartmann & Puri (1974). Based on shell morphology alone, *Phlyctenophora* was chosen due to its precedence over *Ghardaglaia*.

Phlyctenophora grosdidieri Stchepinsky, 1963 was initially described from the central Upper Rhine Graben, and subsequently from the eastern Molasse Basin (e.g. Reichenbacher et al. 2004). Stchepinsky (1963) does not give an indication about the morphology of the marginal pore channels nor the muscle scar pattern, but the rest of the valve morphology applies to our material (with no other similar species described for the basin). Müller (1985) and Reichenbacher et al. (2004) describe the presence of three morphotypes ("broad", "intermediate" and "slender").

The morphologically very similar *Pontocypris oligocaenica* Zalányi, 1929 has been tentatively been assigned to *Phlyctenophora* in Brestenská (1975). The only difference of the specimens figured in Brestenská (1975) relative to *Phlyctenophora grosdidieri* result in a slightly blunter and somewhat higher positioned posterior end and a more well rounded, somewhat larger anterior end of the left valve. The figured specimens in Reichenbacher et al. (2004) seem to represent intermediate forms with a posterior end similar to *oligocaenica*, but an anterior end as in *grosdidieri*. The validity of the precedence of *Phlyctenophora oligicaenica* thus remains to be verified.

Type locality and horizon

Drilling DP-30 near Entzheim (France), sample horizon 176 m, "Stampien supérieur", "Marnes à Cyrènes" sensu Stchepinsky (1963).

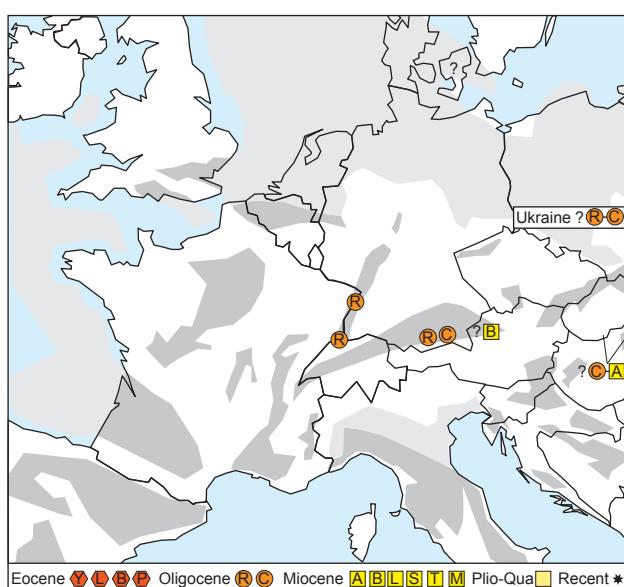

Holotype

A.S. 15, depository not given.

Geographic and stratigraphic distribution

Phlyctenophora grosdidieri occurs in the Rupelian of the Upper Rhine Graben (Oertli 1956; Stchepinsky 1963; Picot 2002), the Rupelian to Chattian of Bavaria (Witt 1967; Hagn & Moussavian 1980; Müller 1985; Reichenbacher et al. 2004).

Potential records hail from the Rupelian to Chattian of the Ukraine (Scheremeta 1969), the Chattian to Aquitanian of northern Hungary and southern Slovakia (Brestenská 1975) as well as the Burdigalian of northern Austria (Kollmann 1971), depending on the future taxonomic status of *Pontocypris oligocaenica* Zalányi, 1929.

Taxonomic remarks

Amphicythere confudens Oertli, 1957 is the only confidently identified reworked Jurassic species. *Schuleridea* n. sp. sensu Oertli (1959) from the Porrentruy area was apparently never definitely described as type. The remaining two specimens cannot be assigned taxonomically with certainty due to very poor preservation.
