The authors wish to acknowledge a mistake in the Related Work Section of the paper “*Conflict-Free Chromatic Art Gallery Coverage*” [1], where we mentioned conflict-free colorings of hypergraphs. In the conflict-free coloring of a hypergraph H , every edge e (a subset of vertices) must have a vertex that is uniquely colored among the vertices in e . For instance, consider the geometric hypergraph induced by axis-aligned rectangles: Its vertices correspond to a finite set of axis-aligned rectangles, and each maximal subset of rectangles with a common intersection forms a hyperedge.

We erroneously wrote that for these hypergraphs, the conflict-free chromatic number has a tight $\Theta(\log n)$ bound, but in fact only an upper bound of $O(\log^2 n)$ (shown by Smorodinsky in [3]), and a lower bound of $\Omega(\log n)$ (given by Pach and Tardos in [2]) is known.
